And now, finally, I shall consider one other class of institutions, namely, sanitariums having for their object the care and treatment of persons suffering from organic and functional nervous disease. These institutions are of all sorts, kinds and descriptions and they are found in all parts of the country. They are large and small; meagerly equipped and elaborately equipped; they are operated by religious associations and by commercial companies and by individuals; they are ethical and semi-ethical and quackish in character. And after a large experience with them, covering something like a score of years, I am bound to say that, generally speaking, sanitarium treatment in this country leaves much, very much, to be desired. My objections to sanitariums are various. This one is entirely too large and has too many patients and too large and complicated machinery and possesses the "sanitarium atmosphere" which is oppressive and depressive. Another is small and badly equipped and affords too little diversion; treatment is slovenly and routine. It appears to me that it is perfectly proper and desirable that sanitariums should afford an opportunity for religious devotions, but it also seems highly objectionable to me that a religious atmosphere should be forced or obtruded on patients. Again, we find that some articles of diet are recommended and others prohibited which are in ordinary use, and thus patients run a great risk of becoming diet cranks. We see sometimes an elaborately equipped sanitarium with all sorts of apparatus, all of which looks very impressive to the casual visitor, but which is too often used improperly. It is used improperly, I believe, when used unnecessarily or too frequently, or when the ends to be gained are not properly considered. I have known more than one self-centered, introspective patient to be made worse by the constant round of ill-planned or unplanned examinations and "treatments" in sanitariums. Again, there may be an excellent medical man at the head of a sanitarium; but the physician finds that when this patient goes to the institution he did not see this excellent chief, but an underpaid and inadequate subordinate. Generally speaking, sanitariums do not sufficiently provide for outdoor games, exercises, walks and varied amusements; and the treatment is slovenly and too mechanical and routine.

Instead of going further into the matter of my objections to sanitariums as I have found them, I shall endeavor to make a little sketch of the ideal sanitarium as I see it in my mind's eye, and as one often finds it abroad; and as one very, very seldom sees it in this country.

It is not very large; it accommodates from 50 to 100 patients. It is situated in the country about three-quarters of a mile from the railroad and is reached by a charming drive; it is in the midst of a very charming landscape in which are found no objectionable features. A large wood in the neighborhood belongs to the sanitarium and has many paths and walks running through it, and these are marked off so that patients can estimate the distance they have walked. Scattered along these walks at intervals are various benches and a few pavilions.

A stable is attached to the sanitarium; drives in the neighborhood are attractive and varied. In a separate building, but very close to the sanitarium and connected with it by a passage way, is an amusement hall containing auditorium for private theatricals and concerts, etc., and in the basement there are billiard tables and a bowling alley and a swimming pool, all of which are used every day. Closely adjoining the amusement hall there is a small but well-equipped bathing establishment with Turkish baths and other provisions for hydrotherapy. Those taking Turkish baths have easy access to the swimming pool.

Now as to the sanitarium itself. It has been especially built and equipped for sanitarium purposes. The building is modest and attractive and entirely free from any freakish design. It has a home-like appearance. The furnishings throughout are simple and modest and thoroughly good, and the whole place throughout is absolutely clean. Nothing is obtrusive. The physician in charge is a man well known for his excellent general character, his ethical standing and his sound conservatism, and the fact that he keeps in touch and abreast with the medical world of the day. In short, he is a man of experience and soundness of character and he possesses tact in a high degree so that he gets on well with the various patients. His position is secure and his time is wholly devoted to his medical duties. He never hesitates to recommend the dismissal of a patient when such dismissal seems to be for the best interests of the patient or the institution. When patients become insane or unmanageable he has backbone enough to demand their dismissal and that they be placed in a proper institution.

The physician in chief is assisted by one or two younger medical men who breathe the atmosphere of their chief and work in complete harmony with him.

The various apparatuses for laboratory work and investigation and therapeutic purposes are at hand. These are used with caution and discretion and not in blind routine fashion and seldom needlessly. One of the main features of the sanitarium is the stress laid on individual treatment; and the doctor avoids, so far as possible, cut-and-dried routine in all his examinations and treatments. The rules governing the sanitarium are simple and clear. Nothing is obtrusive or "peculiar" in these rules regarding religion, diet or anything else. The dietary is simple, but sufficiently varied and thoroughly good. A short religious service is held every day, and any one can go to it; it is held in a place apart and is not in any way obtruded on those who do not wish to go and no one is ever pressed to go.

This is to my mind, as nearly as I can picture it for myself, the ideal sanitarium. The rates are a little high; but not higher than they ought to be considering what the patient gets. And whether or not you accept this ideal sanitarium, I believe that there is to-day a great need and growing demand for better sanitarium treatment in this country.

Westinghouse Building.

THE BASAL PRINCIPLES OF VACCINE THERAPY*

J. G. ADAMI, M.D., F.R.S.
MONTREAL

Perhaps it is as well that the time allotted to me this afternoon only permits that I should, as it were, expose before you the broad ground plan of the territory of vaccine therapy. To criticise adequately but one of the many moot points would in itself occupy more than the given period.

Thus, therefore, in the first place as the main basal principle, it may be laid down that bacterial infection is primarily local and that even when the microbes spread from the primary focus, nay even when a bacteriemia is set up, there still persist tissues of election in which alone those bacteria find conditions for active growth. We may put this otherwise and say that *when bacteria gain entrance to the system they find but a limited opportunity for growth, nay indeed, they are destroyed in, if not by, the majority of the tissues.* Let me afford a familiar instance. Consider the course of a malignant streptococcus endocarditis. The very development of the endocardial lesions demonstrates that the streptococci have been circulating in the blood. Make blood cultures in such a case and without difficulty growths of the streptococci are obtainable. There is no question about the bacteriemia. But in such a case how rare it is to find a true abscess in the spleen, with active proliferation of streptococci in that organ! That the spleen becomes potentially infected is obvious enough; the conditions of the circulation here are just such as to filter and to arrest bacteria brought by the blood; and this organ is one of the seats of election for the arrest of loosened vegetations with their mass of included germs. Infarcts are common enough, but how infrequently do these pass on to true abscess formation! The only conclusion we can reach from this and other cases is that the splenic tissue indifferently destroys the various bacteria brought to the organ and possesses this power to an extraordinary degree. And what is true of the spleen is true also of some of the most widespread and some of the most important tissues of the body. How extraordinarily rare, for instance, it is to find abscesses developing in the skeletal muscles in a case of bacteriemia, or in the liver; or in the brain and cord. In all these tissues the capillary network is so fine that it is impossible that bacteria conveyed by the blood do not become arrested. And here in passing it must be laid down that in the normal animal it is not the circulating blood that itself destroys them. If, as Briscoe has shown, bacteria be introduced into the ventricle of an excised heart, clamped at the auriculo-ventricular groove in such a way as to preclude clotting of the contained blood, then the bacteria undergo little or no destruction on the part of the blood; they are not even taken up by the leucocytes, or more accurately the amount of phagocytosis is minimal. Nor again is it the specific cells of the various tissues to any marked extent that destroy the bacteria, with the exception of the hemolymph system, and I may add as a private heresy, probably the liver. As can be seen by inoculating bacteria into the circulation, killing within a quarter of an hour and making sections of the liver and other organs, those bacteria are actively taken up and destroyed by the endothelial cells lining the capillaries of these organs.

---

* The opening address of a Symposium on Vaccine Therapy, at the meeting of the Association of American Physicians, at Washington, May 4, 1910.

This fact, then, that bacterial infection is primarily local carries with it the corollary that *there is a natural or indifferent or non-specific immunity toward most bacteria exhibited in most of the tissues of the organism.* This, it is true, has its limits; it can be overcome by the exhibition (mostly under experimental conditions) of excessive numbers of bacteria, or of smaller numbers of bacteria of exalted virulence, its extent also varies as regards any particular species of bacteria in the different tissues. But I would lay stress on it inasmuch as it has been too much neglected. It fails to be demonstrated by experiments *in vitro* and so is apt to be overlooked, nevertheless, it is of high importance in this matter of vaccine therapy.

It is the existence of this natural and cellular immunity possessed, with the limitations above noted, by most of the tissues of the body in relationship to any specific bacterial form that renders vaccine therapy possible. Time forbids that I should discuss the most interesting and important matter of its relationship to acquired immunity.

The second great underlying principle to be recognized is that once bacteria have established themselves within a given tissue and have undergone proliferation there, that in itself is a sign that that particular tissue is not immune, that the subsequent arrest of their growth is not due to an exaltation of the bactericidal powers of the local tissues, but is due to aid contributed by the organism from without.

This is now-a-days so generally accepted that I need but indicate the main facts on which it is based, namely, the leucocytic invasion of the infected locality on the one hand and on the other the evidence afforded by Bier's treatment that the local proliferation of bacteria is arrested by favoring the inflow of exudate into the part. I would but call attention to Hektoen and Carlson's[1] recent brilliant and convincing demonstration that just as the natural or non-specific immunity is cellular and not humoral, so the antibacterial substances are not elaborated in the blood itself but in the tissues; that the circulating blood to which toxins have been added is rapidly deprived of those toxins and now transfused into another animal of the same species sets up no production of antibodies in that animal, whereas, the original recipient of the toxins, although deprived of its own blood and transfused with that of a third animal, proceeds to develop immune bodies.

These are the two basal principles, but in order to utilize them, and by introducing the specific bacteria, either living or dead, away from the primary focus of the bacterial growth to induce an increased antibacterial reaction on the part of the other tissues, there are certain precautions to be taken and certain subsidiary principles which must be heeded.

DOSAGE

First, as to dosage. The fact that definite fever and malaise may accompany the development of a (to others) insignificant streptococcus papule, say, on the nose—of a local inflammation not yet elevated to the dignity of a pustule, still less to that of a good honest boil—is a clear indication that a minute growth of a not specially virulent microbe may nevertheless induce pronounced general reaction; or otherwise, minute amounts of toxins are capable under natural conditions of setting up a profound systemic response. The fact noted by more than one observer,[2] that the application of a minute quantity of tuberculin to the skin slightly scarified is adequate to induce an inflammatory reaction around tubercles of the iris, shows similarly that incredibly minute amounts of toxin gaining entrance into the circulation can produce effects, even if in this case it be in a tissue that is sensitized.

It must ever be kept in mind that the first serious endeavor to employ vaccine therapy dates not from Wright but from Koch, or even more accurately from Pasteur, although the latter in his method of preventive treatment of rabies sought to intervene during the incubation period rather than during the frank exhibition of the infectious disease. Koch employed at first extracts of old bacterial cultures as a therapeutic agent, so old that they contained the diffused products of dead bacilli; later, what we now are accustomed to speak of as true vaccines, namely the killed bacilli. He did not at first recognize the significance of administering minimal doses. Wright's brilliant recognition of the possibility of guaging the extent of the reaction that follows hetero-inoculation has, I am inclined to think, been of service not so much as affording an accurate index, as in affording a means of demonstrating that the best results are apt to follow inoculation of doses of vaccine so small that they need induce no systemic reaction obvious during the next few hours by ordinary clinical means. We may thus take it as a generally accepted principle that minute rather than massive doses of vaccine are to be employed.

QUALITY OF VACCINE

As to the qualities of vaccine, what is true regarding preventive immunization would seem to apply to their therapeutic employment, namely, that a more effective reaction and surer results are obtained by the employment of minute non-lethal doses of the specific bacteria, than by the exhibition of dead cultures, and by the latter than by injecting the products of bacterial growth. But inasmuch as in a frank infection we cannot consider the resistance of the organism as normal, and as, in conformity with what has already been stated the virulence or non-virulence of a given microbe and given dose of the same is implicitly determined by its action on the normal organism, so in vaccine therapy it is, in general, unwise to employ inoculations of the living bacteria.*

So also, on general principles, it is obvious that when the various strains of not a few bacteria present wide variations in their capacity to induce the production of the various antibodies in the animals of the laboratory, more constant results are to be gained by the employment of what have been termed autogenous vaccines, namely, the dead cultures of the particular strain of pathogenic bacteria causing the infection in, and isolated from the patient rather than laboratory stock cultures. Such vaccines liberating a particular order of toxins and other bacterial products will more surely stimulate the production of just the particular order of antibodies necessary to counteract and destroy the infective micro-organisms.

CASES SUITABLE FOR TREATMENT

Now as to what may be laid down regarding the cases suitable for this means of treatment. We may broadly express the severity of any given case of infectious disease as the difference between the resisting powers of the organism and the virulence of the microorganism. In other words, a like grade of disease is to be anticipated when the resisting powers are considerable and the virulence of the microbe also considerable, and when the bodily resistance is feeble but the virulence of the microbe also feeble. The most hopeless cases of disease belong therefore to the categories of intense virulence of the specific bacteria, and of extreme depression of the systemic resistance. In neither of these cases, whatever indicator we employ, whether we estimate the agglutinins, the bacteriolysins or the opsonins of the blood do we find other than a lowering of our index of systemic reaction. To inoculate vaccines in either order of cases is, not to set up a reaction on the part of tissues that are exhausted or incapable of stimulation, but is merely to increase the amount of toxic material circulating in the blood, and to accelerate the final event.

---

[1] Jour. Infect. Dis., 1910, vii, 319.

[2] Emery: Immunity and Specific Therapy, London, 1909, p. 381.

* The only exception that I can call to mind is the most cautious method introduced by Williams and Webb of treatment of tuberculosis by inoculating first either a single lung bacillus, or a very few, accurately counted, and at intervals steadily increasing the dose. This demands technical skill of the highest order.

Thirdly, as to the great mass of intermediate forms. what is to guide us? With Wright we may distinguish between two main groups of cases, those in which the growth of the specific organism within the body is accompanied by a febrile state, and those in which a continued febrile state is wanting, although on occasions rise of temperature may show itself. The febrile state is the sign of diffusion from the foci of growth of the bacterial toxins, and possibly also of the products of local tissue disintegration, and of reaction to the same.

With Wright we accept that the non-febrile cases indicate a limited and confined local growth of the bacteria, under conditions which do not readily permit the infusion of lymph either for the continued nourishment of the bacteria or for the conveyance of antibodies, and which, coincidently, arrest the effusion of toxins and products setting up the general reaction. These conditions may be due to the tissue in which the growth occurs being by nature dense and poorly supplied with vessels, or may be of secondary development, the specific microbes being of a relatively low grade of virulence, so that the tissues immediately surrounding the foci of growth instead of being depressed become stimulated to proliferate, whereby there is developed a surrounding capsule, well seen, for example, in connection with many tuberculous foci.

As we see, I might almost say daily, in the postmortem room, in connection with obsolescent tuberculous foci, this capsule formation may be so dense that in itself it must be regarded as a means of arrest of disease; or otherwise we may reasonably deduce that there can be a grade of self-limiting infection which, as there is no general reaction, is a potential rather than an actual infection, and in which vaccination is, it might seem, unnecessary. All the same, bacteria so fenced in are not absolutely innocuous. Clinical and post-mortem room experience demonstrate that they are apt to be latent and not destroyed. It would seem that hyperemia of the surrounding tissue and increased infusion of lymph may stimulate the bacteria to renewed growth and, whether by leucocytic agency or by necrosis and solution of the capsule, the bacteria may escape and set up active infection. The advantage of vaccination in this order of cases is that it replaces an unprepared by a prepared organism, and that through the sensitization of the immediately surrounding tissue it induces a very definite grade of hyperemia and leucocytic infiltration of that tissue, which, if the encapsulation is not too dense, must favor the entrance into the focus of antibacterial agencies; its disadvantages is that owing to the process of encapsulment the prepared lymph and leucocytes percolate with difficulty into the focus and thus are apt to be presented in quantities insufficient to bring about bacterial destruction. Vaccination alone in this stage does not surely bring about cure. What is necessary is the employment of auxiliary methods promoting the freer flushing of the focus or foci with antibacterial lymph as by Bier's methods for inducing hyperemia or Paterson's method of graduated exercise.

Why, it may be asked, do I categorically lay down here that the lymph is the important agent It may well be urged in objection, that, owing to the contradictory results obtained by different observers, one is not justified in concluding that the blood plasma and lymph, as contrasted with blood serum *in vitro,* possess either antibacterial or opsonizing properties, whereas, on the contrary Metchnikoff has proved to the hilt that the leucocytes of an immunized animal possess far more active phagocytic properties than those of the non-immunized. Quite so. But this is to me a very striking fact that neither Metchnikoff nor any of his school have succeeded in proving that the leucocytes of the immunized animal *per se*— the leucocytes separated from the plasma have greater phagocytic powers than those of the non-immune animal. And, this being so, we must hold as the simplest explanation that without the influence of the immune plasma or lymph the leucocytes are relatively inactive. Nor is it an adequate argument to urge that the leucocytes after centrifugalization and washing are depressed in their functions when placed in normal salt solution, if those same leucocytes transferred to serum will take up a score or more bacilli in a quarter of an hour. My colleague, Dr. Meakins, permits me to quote a yet more effective demonstration of this fact, repeatedly made by him, namely, the leucocytes of a highly immune animal placed in non-immune, normal serum do not take up any greater number of bacteria than do the leucocytes of a normal animal placed in the same serum.

We come now to the consideration of those cases in which the diffusion of bacterial products from the foci of growth has already caused a reaction on the part of the organism. Can we vaccinate with impunity in these cases—in the course of typhoid, pneumonia, and other acute diseases attended by manifest fever? Is there not the danger of adding to the amount of circulating toxins, and thereby exhausting the distant tissues—lymphoid, vascular endothelial tissue or what not—rather than the benefit of stimulating them to produce additional antibodies? Here I am inclined to lay down that the fatal event in the majority of severe infections is not brought about by exhaustion of the tissues in general, but by action of the circulating toxins on the medullary nerve centers, and that the sign of exhaustion of the tissues or paralysis of the same and inadequate reaction on their part is a lowering and not a rise of the body temperature. Thus in the first place it may be laid down that, to guard against excessive action on the nerve centers, *vaccination should never be directly into the blood stream but should be subcutaneous,* allowing a slow percolation of the added bacterial products into the lymph and blood; and, in the second place, that the febrile temperature as such is the evidence of capacity on the part of the tissue to react. This may, I think, safely be laid down that on the one hand a sinking temperature accompanied by increased weakness of pulse and respiration and advancing "toxic" state is a clear signal that the reactive powers of the patient are being overcome and exhausted, so that vaccination can only be harmful, and on the other hand if the fever be somewhat high, provided that the pulse is steady with no signs of cardiac weakness, then vaccination may safely be undertaken. The good results obtainable in these cases can no longer be questioned, and what is interesting is that the system evidently benefits from the slight temporary added rise of temperature which shows itself during the six hours or so immediately following the vaccination.[3] Hyperpyrexia is a contraindication.

Time forbids me to do more than note the curious paradox that often such vaccination converts a disease like typhoid that ordinarily recovers by lysis into one recovering by crisis, and *vice versa* time and again causes a disease like pneumonia culminating in crisis into one healing by a relatively slow but favorable lysis. I can only emphasize that the physician must be prepared for these modifications of the normal course of disease.

THE OPSONIC INDEX

In conclusion there remains to be noted what Wright—and rightly—made the guiding principle in the development of his methods of vaccine therapy, namely, the establishment of an index whereby to determine the effects and course of the subsequent reaction. This was a notable advance. Nevertheless, serviceable as it has been in establishing vaccine therapy as a rational procedure and in determining both the intervals that should elapse between vaccinations and the augmentation of successive doses, it has to be admitted that Wright's index is faulty. The principle is all important, the means of *application of the same imperfect.* When two of the leading experts in London working with samples of the same blood taken before and after vaccination can report, the one that the index is raised, the other that it is lowered, by the process,[4] when, as pointed out by Meakins,[5] a given serum may afford a higher opsonic index when it is diluted than when it is undiluted, and when, as noted by more than one observer,[2] during a long and continued negative phase, which according to Wright is a danger signal, the patient may obviously be making rapid improvement, something must be wrong. The dilution method introduced by Neufeld and Hüne[6] and employed on this continent by Klien,[7] Meakins[5] and Hektoen[1] clearly reduces the error of the personal equation, and, giving a vastly greater cale of the same order as that employed for the estimaion of agglutinins and lysins, permits a comparison to be made between the opsonins and other antibodies of the erum. But if Wright's method is laborious and time consuming, this is more so. The only practical course to recommend is that, in connection with each particular infection that it is sought to treat, the observer first studies thoroughly the variations in the opsonic and other indices in a series of cases, while carefully observing the effects of the vaccination treatment at the bedside, and then, armed with this foundation knowledge of the results of different strengths of doses in the different orders of cases, he educates himself to depend more and more on clinical symptoms in determining the strength and the frequency of his inoculations. Thus as shown by Latham[8] and by Hort,[4] it is possible in tuberculosis to read a temperature chart in terms of an immunity curve, the latter employing not the daily variation but joining the evening temperatures into a continuous curve.

In short vaccine therapy to be a success must be undertaken, not by the busy consultant, nor again by the confirmed habitué of the laboratory, but must be placed in the charge of one who, combining a thorough laboratory training with a certain amount of time not consecrated to other engagements, and a recognition that his future field lies in clinical medicine, accepts gladly the opportunity here afforded to apply his technical knowledge and to make intimate studies of individual cases of disease. Vaccine therapy lies in the hands of those younger well trained physicians whom happily the foremost schools of this continent are producing in increasing numbers.

Thus as a final principle it may be laid down—and I do this with full sense of the necessity and of the responsibility that attaches thereto—that vaccine therapy is not to be undertaken by the ordinary practitioner; there are too many dangers attaching thereto; and with this the corollary that, excellent as may be the stock vaccines prepared by certain firms, to advertise these lightheartedly and recommend them and their employment far and wide deserves the condemnation of this Association and of all interested in the well being of their fellow men.

---

[3] A rise which, it is interesting to note, is wanting in the class of limited infections already discussed, and is suggestive of increased sensitiveness of the tissues already stimulated by the circulating toxins discharged from the infected focus.

THE EPIDEMIOLOGY OF POLIOMYELITIS

A PLEA THAT IT MAY BE CONSIDERED A REPORTABLE QUARANTINABLE DISEASE*

JOSEPH COLLINS, M.D.
Physician to the Neurological Institute
NEW YORK

Half a century has elapsed since Heine published the first known description of the disease which is now commonly called anterior poliomyelitis, or as he designated it, spinal infantile paralysis. Half a century is an extremely short time for a disease so hideous and uncompromising to hide the secret of its being; it might have done so much longer had it not been for the ghastly epidemic that occurred in New York in 1907, which permitted Flexner to initiate the experiments from which has flown his brilliant discovery of its cause.

EPIDEMICS

Poliomyelitis has prevailed epidemically in many parts of the world during the past twenty-five years. The great epidemics have been, that of Norway in 1887 and 1895; 43 cases in the first, and 20 in the second, recorded by Medin; that of Rutland, Vermont, in 1894; 126 cases, recorded by Caverly; that of Queensland in 1904, 108 cases, recorded by Ham; that of northern Norway in 1905, 437 cases, and of southern Norway in the same year, 103 cases, recorded by Wickman; that of Vienna in 1908, 266 cases, recorded by Zappert; that of Wisconsin in 1908, 352 cases, recorded by Manning; that of Rhenish Westphalia in 1909, 500 cases recorded by Rekzheh, Krause and others; and the New York epidemic in 1907, 2,500 cases, recorded by a collective investigation committee in 1909.

In 1908 Holt and Bartlett[1] collected the literature of thirty-five epidemics which had occurred prior to the year 1907. Since that time about twenty epidemics, large and small, have been reported. Reference to the literature of these latter epidemics are appended to this article. The literature of the early epidemics will be found in the article by Holt and Bartlett.

---

* Read before the Association of American Physicians, May 2, 1910.

[1] Amer. Jour. Med. Sc., 1908, lxxxv, 647.

The large number of cases in the recent epidemics indicate that many cases formerly diagnosticated as grip, rheumatism, neuritis, bulbar paralysis, etc., are now recognized to be clinical varieties of poliomyelitis. It is the signal service of Wickman to have emphasized the various clinical forms under which the disease may display itself.

A NEW DISEASE

The most remarkable secular mutation of poliomyelitis is that it is apparently a new disease. So far, nothing has been found in the literature to indicate that previous to 1843 the disease existed. In that year Colmer published[2] the report of a case of infantile hemiplegia that he had seen in West Feliciana, Louisiana, and brief mention of ten other cases of various forms of paralysis occurring in children which were probably dependent on poliomyelitis. It is worthy of remark that cerebrospinal meningitis escaped recognition up to the year 1834. The unheralded advent of a disease of which no trace has been met in history, is not uncommon. The English sweating sickness made its appearance abruptly in 1486, and disappeared with equal abruptness in 1551.

Because of the short time that we have been familiar with epidemic poliomyelitis we are unable to say whether or not it is subject to the alternating periods of quiescence and recrudescence that are so common in other epidemic diseases. In this country it has not prevailed epidemically twice in the same place, unless the mild epidemic of 1909 in that portion of Brooklyn known as East New York may be so considered, nor can we say that it displays conspicuous multiannual nutations, to use Ransome's designation for fluctuations in prevalence and virulence extending over periods of from ten to fifty years. Poliomyelitis may be constantly more or less existent in a densely populated large city such as New York, but its existence is known only to individuals who may come in contact with it. When the disease shall be put on the list of reportable diseases, then it can be determined what its multiannual fluctuations are. One fact that is worthy of attention, is that during the epidemic of 1907 in New York, the death rate from other epidemic diseases was not lower than it usually is. This is contrary to what has been noted in other epidemic diseases. For instance, when scarlet fever prevails, the death rate of measles is apt to be low and *vice versa.*

SEASONAL OCCURRENCE

The most remarkable thing in the epidemicity of poliomyelitis is its seasonal occurrence. It occurs as invariably in the summer months as smallpox does in the winter months, and the advent of cold weather seems to terminate epidemics in every instance. One may readily draw the inference from this, that cold is inimical to the saprophytic growth of the non-obligatory parasite, but to make such inference legitimate, it would first have to be proved that the virus is parasitic in nature. In several instances it has been noted that the summers have been particularly dry. The only exceptions to this are a small epidemic reported by Litchfield, of Sydney, who notes that the summer was wetter and cooler than usual, and one in San Francisco in May and June, 1901, reported by Woods,[3] in which there were fifty-five cases.

COMMUNICABILITY

The next most interesting feature of epidemic poliomyelitis is its communicability. Until recently it has been a matter of personal opinion whether or not the disease was communicable. Those who have reported epidemics have expressed their conviction that the disease was probably contagious and such occurrence as that reported by Pasteur,[4] in which seven cases occurred in one family, seemed to leave no doubt of the contagiousness of the disease. The description of an extensive epidemic in Stockholm in the summer of 1899, in which in various houses two cases of the disease occurred, and in several families, in which two or three cases were observed amongst relatives who had had contact with the sick, went far to corroborate this belief, and when Geirsvold was able to trace the disease from one village to another, and from one house to another, the contagiousness of the infection began to be realized. Since the publication by Wickman[5] of the epidemic which occurred in the summer of 1905 in southern Norway, the contagiousness of the disease has been admitted. In the majority of instances some contact could be traced between one patient and another, and even the spread of the disease from one village to another could be traced by the passage of the individuals from town to town.

The most remarkable contribution to the study of its contagiousness, however, has been made in our own country by Dr. George P. Shidler,[6] of York, Nebraska. Dr. Shidler seemed somewhat in doubt whether the spinal disease which prevailed epidemically in York county in July, 1909, was poliomyelitis or cerebrospinal meningitis, but there can be no doubt that it was the former. Some of his cases are most illuminating in showing the contagiousness of the disease. For instance, a woman went with her child to the wedding of a sister in whose house a younger sister was ill with the disease; nine days afterward the mother, with the child, returned to her own home another of her children came down with the disease. In an adjoining house there lived a family of six children; all of them developed the disease; a woman who came to visit this family brought her baby; in five days it died of the disease. Soon after this, quarantine was established, and the disease was checked. A number of other instances quite as striking as this are published, but the most important contribution to the epidemiology of the disease, is the number of cases that occurred in families in which there were two or more children, all of whom acquired the disease. There were six cases in a family of six children; four cases in a family of six, four cases in a family of five, four cases in a family of four.

Contact with a person sick of the disease is not necessary that another person may contract it. There are numerous examples of contagion by indirect contact; that is, a person who does not have the disease carries it from a victim of the disease to another at a distance, who then falls ill of it. This has been established by the record of several epidemics, but by none more strikingly than those reported by Wickman and by Shidler.

INCUBATION, DISTRIBUTION AND MORTALITY

The period of incubation may be as brief as four days, or it may be a fortnight. From a study of their publications alone, it must be accepted that poliomyelitis

STATISTICS OF EPIDEMICS

Year and Season.	Locality.	Topography and Hygienic Surroundings.	Number of Cases.	Deaths.	More Than One Case in Family.	Author.	References.	Remarks.
1907 Summer and early autumn.	Sweden.	Towns and country.	100 in the epidemic of '05, 50 in '06.	159 corrected mortality. 16.7%.	Many examples.	Wickman	Beiträge zur Kenntnis der Heine-Med. Krankheit, Berlin, 1907.	The most complete presentation of the subject extant.
1907 Summer.....	Pennsylvania. Ridgway......	County—good....	50	4	No...........	Terriberry....	Long Island Med. Jour., Dec. 1907.	The disease extended down the valley in a definite direction.
1907 Summer.....	Michigan. Oceana Co....	....	20	Not given.	No...........	Griffin........	Jour. Michigan State Soc., Feb., 1908.	Meningeal symptoms were common. Pigs and chickens also affected.
1907 Summer.....	Pennsylvania. Dubois.......	County and village.	100	A few.....	....	Free..........	Jour. Nerv. and Ment. Dis., Apr., 1908, a brief abstract of paper read before the Phila. Neurological Soc.	
1907 Summer.....	Wisconsin. Galesville....	Rural............	22	....	....	Jegi	Wisconsin Med. Jour., Apr., 1909.	
1908 August to October.	Wisconsin.	Bad sanitation and sewerage; surface wells in marsh and near privy.	352 in the state. 167 in Eau Claire County.	54	....	Manning......	Wisconsin Med. Journal, April, 1909.	29 cases followed direct exposure to infection; 25 cases immediately after a case in same house; 2 in houses where disease prevailed 3 and 20 years before.
1908 Summer.....	Minnesota. Moose Lake, Barnum, Wadena.	Rural............	....	....	In 1 family of 6 children, 5 ill; 2 died, 3 recovered; another of 5 children, 3 ill, 1 died.	Hamilton	Wis. Med. Journal, April, 1909; Northwestern Lancet, Minnesota, Oct., 1909.	Disease assumed type of neuritis; several patients had tonsillitis.
1908 Summer.....	Michigan. Flint.........	Rural and village.	30	5	One family: 2 little girls within a week.	Manwaring ..	Jour. Michigan State Med. Soc., April, 1909.	
1908 Hot, dusty weather.	Minnesota.	Good hygienic surroundings.	....	....	A few cases only; no isolation of any cases.	Hill	Northwestern Lancet, Sept. 1, 1909.	No evidence of the transmission of the disease from person to person or through infected houses or water, or by animals or by dirt-eating (common among children eating raw vegetables direct from the garden).
1908 April-June after dry weather.	Australia. Victoria......	Densely populated districts; sanitation fair.	137	6	Majority of cases in families where 3 or 4 slept in same room or same bed.	Stephens.....	Intercolonial Med. Jour. Australasia, Nov. 20, 1908.	No severe pain in disease. Incubation period 3 to 16 days. Invasion, 0 to 7 days.
1908 July to September.	Minnesota. Northfield....	....	20	4	4 in 1 family; 3 in another; 2 in another.	Strang........	Jr. Minn. State Med. Assn. and Northw. Lancet, July 1, 1909.	
1908 June to September.	Virginia. Salem........	Town and vicinity.	25	3	No 2 cases in 1 family, even when other children were exposed.	Wiley and Darden.	THE JOURNAL A. M. A., Feb. 20, 1909.	Cool weather interrupted epidemic for 3 weeks; then hot weather brought on 2 new cases in August. Patients had pronounced hyperesthesia and sweating.
1908 June to September.	Massachusetts. Western part.	3 contiguous and 11 neighboring towns, on banks of streams; detached houses, no sewers in majority of houses. Sanitation not good.	69	5	2 cousins in same house, 2 brothers in a family, 2 cousins in another, 2 brothers in another, 2 sisters in another.	Lovett and Emerson.	Monthly Bul. Massachusetts State Board of Health, July, 1909.	All patients were exposed to valley influences. No correlations to curves of the temperature, rainfall and number of cases. Two to three times the number of children sick were exposed and did not become ill. Six patients over age of 17.
1908 Summer.....	Westphalia. Hagen........	Not remarkable. (See note.)	100	Not stated: 9 autopsies.	....	Krause.......	Deutsch med. Wochenschrift, Oct. 21, 1909.	Great mortality among chickens. Shoots of small oaks covered with white fungus.
1908 Summer.....	Vienna and Lower Austria.	Ordinary; not bad.	266	....	....	Zappert......	Wiener med. Wochenschrift, Nov. 13, 1909.	
1908 Summer.....	New York. Schenectady.	Good............	29	....	....	Clowe........	Albany Medical Journal, vol. 19, 1908.	
1908 Summer.....	Germany. Marburg.	....	50	....	....	Romer and Muller.	Münchener med. Wochenschrift, Dec. 7, '09; ditto, Nov. 30, 1909.	Sore throats extremely common. Many examples of communicability from person to person.
1908 Summer.....	Pennsylvania. Lewiston.....	....	30	3	Two	Barnett	Therap. Gazette, Sept., 1909.	
1908 Summer.....	England. Essex	....	8	None......	Three and two.	Trevis........	Brain, Nov., '09.	Could not trace spread of disease.
1909 Summer and autumn.	Rhenish Westphalia.	....	500	18.2 in 1 vicinity.	....	Rekzeh.......	Med. Klin.. 1909. No. 45, p. 1704.	It followed an outbreak of acute poliomyositis.
1908 Summer.....	Russia.	Not remarkable.	49	....	Several instances.	Schwarz......	St. Petersburg Med. Wochenschrift, Jan. 10, 1909.	In a village of 500 inhabitants.
1909 Summer.....	Nebraska. York County.	Hygienic surroundings good—fair.	200	15 =7.5%	Over 1 in family; 44% occurred in families with more than 2 children, all of whom took the disease.	Shidler.......	THE JOURNAL A. M. A., Jan. 22, 1910.	Shows the necessity of having epidemics properly studied. Perhaps the most important on record. The report is unfortunately fragmentary.

is a contagious disease. That its contagiousness varies needs scarcely be said. In the New York epidemic, the most extensive on record, the only evidence of its contagiousness was that there were two or three cases in a few families, but the most painstaking care to detect any evidence of its communicability was unrewarded.

The territorial distribution of some of the epidemics is noteworthy, especially the epidemic of Sweden in 1905. Although the disease was pretty generally distributed through the entire country, there were well-marked foci in which the disease was prevalent to a considerable extent, or to a slight extent, and the large intermediary areas in which the disease did not exist. This has been noted in several other instances, but in the New York epidemic there certainly were no foci of the disease. The disease has no apparent relationship to density of population.

The next most important fact obtainable from a study of these epidemics is that the mortality rate varies very decidedly in different epidemics. In some it is as low as 5 per cent., in others it is nearly 20 per cent. (the highest ever recorded was in an epidemic in Sweden in which the death rate was 46 per cent.) The former figures approximate the death rate in the New York epidemic, the latter that in York county, Nebraska.

INFLUENCE OF SURROUNDINGS

The most careful investigations have failed to reveal that the epidemic prevalence of the disease has anything to do with unhygienic surroundings. To be sure, in some instances it was noted that the sanitary conditions were poor, especially in some of the epidemics of Norway, (Geirsvold) but in the majority of the large epidemics such as those of Vermont, New York, Nebraska, Australia, and Westphalia, the hygienic conditions were good, and in some instances excellent.

The association of poliomyelitis occurring epidemically with other diseases has been made a rather important feature by many writers, and there are in the literature a number of cases showing such association. As a matter of fact it has no noteworthy relationship to infectious diseases. In several instances there was a great mortality among chickens (Caverly, Krause) and the latter writer made the interesting observation that the shoots of small oak trees surrounding a house in which several cases occurred were noted to be covered with white fungus. This disease of the young oak shoots had only existed for a short time. This author also observes that there was a great number of cases among breast-fed children, and a number of writers point out that disorders of the digestive organs were very common. Personally, I made a close study of this question in the several hundred cases that I saw in the New York epidemic, and the conclusion that I drew was that digestive disturbances had no relation to the occurrence of the disease.

RECRUDESCENCE

A very remarkable fact was noted by Stephens[7] that there was a recurrence or recrudescence of the disease occasionally observed in the same child. Dr. A. A. Eshner thinks that he has observed a second attack of poliomyelitis in the same patient. It is most probable, however, that one attack of poliomyelitis gives immunity for a long time.

MODE OF INFECTION

We need no longer conjecture whether or not the disease is contagious. The points for our consideration are; what the spreading powers of the virus are, and what the facilities are for the spread of the contagion, and how does it gain entrance to the system. Spreading powers of the virus vary unquestionably with the epidemics. In some cases apparently it is impossible to make it out, and in other cases, as in the Nebraska epidemic and in the Westphalia epidemic, the spreading powers of the virus were commensurate with social contact, and the facilities for the spread of the contagion depend on such contact. From a study of the disease clinically, no information has been obtained as to how the virus gains entrance into the system. From experiments on monkeys, however, Flexner is convinced that the portal is the same as in epidemic cerebrospinal meningitis, namely the nasopharynx. The necessity of adopting measures to keep this mucous membrane in a state inimical to infection in children of a community in which the disease is prevailing is obvious. The period of incubation is from five to ten days. It may be longer in some instances, and quarantine for a fortnight or longer would seem to be proper.

NEED OF QUARANTINE

Boards of health should be urged at once to place poliomyelitis on the list of reportable diseases and to formulate measures which may be quickly enforced to constitute the strictest quarantine. Although the death-rate is comparatively low in some epidemics, it is apparently high in others, and our utter inability to influence the disease after it has begun, in conjunction with the fact that it maims the vast majority of those that survive it, should spur us to every effort, individually and concertedly, to stamp out the ghastly disease. That quarantine shall be of real value we must learn to detect the so-called atypical cases, particularly the "meningeal" cases, and those in which paralysis does not occur.

PATHOLOGY AND DIAGNOSIS

We must forget the description of the text-books and realize that poliomyelitis is an acute infectious disease of the cerebrospinal axis and its covering, the pia, with a pronounced and inexplicable predilection for the gray matter of the anterior portion of the spinal cord, which it nearly always succeeds in affecting before its pathogenic impetus is satisfied. But it affects the gray matter in one case profoundly; in the other triflingly, and the symptoms that result must of necessity vary with the intensity of this affection and with the portion of the cerebrospinal axis that bears the brunt of the lesion.

We must also learn to diagnosticate the disease early, a task more difficult than the interpretation of the so-called atypical cases. It has been recently suggested by Flexner (verbal communication in the discussion of this paper) that in view of the frequency of a degree of leptomeningitis in perhaps the majority of cases, the spinal fluid withdrawn early in many of these cases will show an increase of proteids and changes in the lymphocytes which will suggest the diagnosis before the disease has an opportunity to attack the cord itself. We might legitimately entertain the hope from our knowledge of the diffusion of formaldehyde within the system that soon we may be in possession of a substance which will be adequate to check the progress of the disease.

Strangulated Ovarian Tumor in a Child.—*J. M. G. Swainson* (*Proc. Roy. Soc. Med.*, February, 1910) reports the case of a child aged 2, brought to the hospital with acute abdominal symptoms, pain and vomiting of four days' duration. The abdomen was rigid, somewhat distended, and the temperature was 100.4 F. A tumor was felt in the right iliac fossa. Operation revealed a strangulated ovarian tumor about the size of a tangerine orange and greyish black in color. The other ovary was normal.

PARALYSIS OF THE NECK AND DIAPHRAGM IN POLIOMYELITIS*

IRVING M. SNOW, M.D.
Clinical Professor of Diseases of Children, Medical Department, University of Buffalo.
BUFFALO, N. Y.

The knowledge of the nature and symptoms of poliomyelitis has expanded enormously within the last five years. New ideas of the communicability and pathology of the disease have been accepted. Landry's paralysis, polio-encephalitis, and various painful paralyses are now included in one disease-concept. It is therefore with the hope that an unusual symptom-complex of poliomyelitis may find a place in the literature of the disease that I report a case of high cervical poliomyelitis causing a paralysis of the diaphragm and neck muscles and terminating in complete recovery.

The existing literature on this subject is very scanty.

Neck paralysis in combination with loss of power in the extremities is not unusual; on the contrary, isolated neck palsies are excessively rare in poliomyelitis.

Paralysis of the diaphragm is scarcely mentioned in treatises on poliomyelitis except with the fatal type of Landry's paralysis.

There is but one recorded case (Erb's[1]) of a combined paralysis of the phrenic and spinal accessory nerves existing as the sole lesions of a high cervical poliomyelitis. The origins of the spinal accessory and phrenic nerves are close together on the upper cervical cord. The spinal branch of the spinal accessory originates in the anterior horn of the cord, as low as the sixth cervical nerve. It is simply a motor spinal nerve which has the unusual course of ascending into the skull and of leaving it again with a cranial nerve. In the neck the spinal accessory inosculates with the second, third and fourth cervical nerves and forms a plexus which innervates the sternomastoid and the trapezius muscles.

The phrenic nerve—4th cervical-nerve—arises from about the same tissue and innervates the diaphragm. Thus the two pairs of nerves originate in about the same area of spinal gray matter, and a focus of inflammation in the cervical cord might easily injure the functions of both phrenic and spinal accessory nerves.

The rarity of paralysis of the phrenic nerve may be due to the resisting power of its tissues to disease.

With paralysis of the neck muscles the symptoms are characteristic. The patient cannot rotate the head, hold it erect or raise it from the pillow. In sitting or standing, the head falls forward, backward and sidewise, not following the movements of the body; the head wabbles around on the body like the headpiece of a disabled marionette.

In Wickman's analysis[2] of the distribution of paralysis in the Swedish epidemic of poliomyelitis in 1905 with 479 cases, neck paralysis existed in nine patients. This does not include cases described as Landry's paralysis or paralysis of respiration, or cases of ascending paralysis in which all four extremities and the neck were paralyzed before the fatal issue. Thus, palsy of the neck muscles occurred in 1.9 per cent. of cases of the benign type of the disease; in only one case was there an isolated palsy of the neck. With the others loss of power in the neck was associated with paralysis of the extremities.

From the report[3] of the Collective Investigation Committee of the New York epidemic of poliomyelitis of 1907, one would conclude that loss of power in the neck is common. In 679 cases loss of motion in the neck occurred as the first symptoms in two instances, and at the height of the disease 299 patients (39.8 per cent.) could not hold up their heads. As to this symptom both the questions of the committee and the resulting answers are vague as to whether the inability of the patient to raise his head came from general prostration or from paresis of the sternomastoid and trapezius; yet a fair conclusion is that in a considerable number of cases there existed a motor palsy of the neck.

It is interesting to note that the committee made an analysis of the residual disability in 318 cases in the same epidemic of poliomyelitis and no mention is made of a neck palsy, so that one may draw the conclusion that this symptom generally disappears. That with the neck paralysis of poliomyelitis a complete recovery generally follows may also be inferred from the last edition of Starr.[4]

In an analysis of 1,292 permanent palsies from poliomyelitis collected from the statistics of Starr, Duchenne, Seligmuller, Sinkler, Lovett, no paralysis of the neck is recorded. Starr, however, states that during the disease, the neck muscles are occasionally weak and that the paralysis may extend to the neck, throat, face and even the eyes, giving rise to the symptoms of bulbar palsy, the polio-encephalitis inferior and superior of Wernicke.

Oppenheim and Zappert[5] do not mention paralysis of the neck or diaphragm in their articles on poliomyelitis.

Fetra[6] states that in 63 cases rigidity of the neck existed in eleven cases and a paralysis of the neck and larynx in one case.

Buzzard[7] says that in poliomyelitis there is occasionally a rapid atrophic paralysis of the muscles of the head and trunk; and Holmes states that paralysis of the diaphragm is in the majority of cases only part of a general peripheral neuritis or poliomyelitis.

PARALYSIS OF THE DIAPHRAGM—PHRENIC NERVE

Wickman[8] says that the pathologic disturbances of the mechanism of respiration in poliomyelitis are partly due to an affection of the spinal center of the intercostal muscles and diaphragm, and partly to a lesion of the origin of the vagus nerve. It is not always possible to distinguish whether the respiratory distress comes from a high cervical or a pontine source. An injury to the pneumogastric of medullary origin usually shows itself by recurring attacks of dyspnea and tachycardia.

With an isolated bilateral paralysis of the diaphragm the symptoms are usually very clear. The respiratory abdominal movements are the reverse of normal. In health during inspiration the abdominal viscera are depressed and the abdomen is protruded. With a diaphragmatic palsy the upper abdomen recedes during inspiration and is pushed out during expiration. Breathing is labored and difficult. Any effort causes cyanosis and dyspnea. The lungs are nevertheless clear of pathologic sounds. The prognosis is always serious, partly from the danger of pulmonary infection, and is especially grave if associated with bulbar symptoms. If the paralysis of the diaphragm is complicated with a loss of power of the intercostal muscles the patient will probably suffocate. This danger is greatest in the first week, after which time the outlook improves.

REPORT OF CASE

The history of my case of cervical poliomyelitis causing paralysis of the neck and diaphragm is as follows:

Patient.—John D. was a boy of 4, a patient of Dr. Villiaume. Previous to his illness a baby brother, breast-fed, had sickened August 29 with fever, vomiting, diarrhea and general tenderness and died in a few days; and a cousin, also in the same house was attacked with symptoms of meningitis and taken to Ohio. Both these were probably cases of poliomyelitis spreading by direct contagion. John D. sickened September 4, with pain and tenderness in the limbs, trunk and neck, vomiting, fever, 104, pulse 150, and retention of urine. Later the pain and tenderness lessened, but there was still soreness and muscular twitching in the limbs, and in a day or two a flaccid palsy developed in the muscles of the neck. There were no convulsions; the boy was slightly delirious at times.

Examination.—I saw the patient first September 8, the fifth day of the disease. He was a well-developed boy, lying in a reclining chair, breathing with great difficulty. The pulse was 110, regular; respiration 42. The lungs were clear; there was a complete paralysis of the neck muscles so that the patient had no control of his head. The head fell backward and forward and sidewise unless held with the hands or resting on a pillow. The neck was not tender. Its muscles did not respond to the galvanic or faradic current. Evidently there was present a paralysis of both spinal accessory nerves injuring the function of the sternomastoid and trapezius muscles. Most of the child's distress arose from difficulty in breathing. The whole chest moved with great effort during respiration. With inspiration there was slight recession of the anterior ribs and the upper abdomen was drawn in; it bulged out at expiration, indicating a bilateral paralysis of the diaphragm. The right knee-jerk was absent, the left normal; sensation was normal.

Course of Disease.—In the evening there developed great cardiac depression, rapid pulse and intense dyspnea, giving rise to the fear that the myelitis had invaded the medullary tract. This distress passed away in a few hours. After this for ten days the child remained in stationary condition and was fairly comfortable except that the respiration was labored and rapid and that the neck muscles were useless.

September 17: Fourteenth day of illness. Dr. James W. Putnam in consultation. There was no fever; respirations 40, pulse 120 to 140. The face was often flushed; the pupils were evenly dilated; the lungs were clear; the heart sounds good. The neck muscles were still paralyzed; did not respond to faradism. The abdominal muscles responded to faradic current; the upper abdomen receded at inspiration. Evidently the condition was due to a high cervical poliomyelitis affecting a focus at the origin of both pairs of phrenic and spinal accessory nerves.

October 21: Forty-seventh day of illness. There had been general improvement since last mentioned date. Respirations were 31; pulse 96. Both knee-jerks were lost. Respiration was easy and normal. The abdomen bulged at inspiration; the abdominal reflexes were good on both sides. The head could be moved rather feebly from side to side and also drawn forwards. The sternomastoid was partly restored. The head could not be moved backwards. There was no power in the trapezius; all the neck muscles wasted and flabby; all twitch with the galvanic current.

The paralysis of the diaphragm began to improve after the third week and had disappeared by the sixth week. The child improved rapidly in health. A jury-mast support enabled him to support his head. About March 1 the jury-mast support was discarded and the child played about without artificial support to his head. All of the muscles of the neck could be moved, although the sternomastoid was still somewhat weak. There was no apparent wasting of any muscle. The course of the disease showed that the myelitis affected a small focus in the cervical cord between the third and sixth cervical nerves, temporarily destroying the function of both phrenic and spinal accessory nerves; the lesion about the phrenic nerve caused a severe but temporary disturbance of respiration. The paralysis of the neck muscles lasted about four months, after which time both sternomastoid and trapezius recovered their power.

The treatment—protection from chill and respiratory infections, rest, diet, strychnin, electricity—was skilfully carried out by Dr. Edward Villiaume.

CONCLUSIONS

From the meager literature of paralysis of the neck and diaphragm in poliomyelitis I would draw the following conclusions:

1. Cervical poliomyelitis affecting only the origins of the phrenic and spinal accessory nerves is rare, but in the two recorded cases recovery occurred.
2. Paralysis of the neck muscles occasionally occurs in poliomyelitis and except in Landry's paralysis the prognosis is favorable as to restoration of function; some improvement always takes place.
3. Paralysis of the diaphragm is exceptionally seen in poliomyelitis and that, although dangerous, recovery is possible.

476 Franklin Street.

THE PROBLEMS OF THE PHYSICIAN CONCERNING THE CRIMINAL INSANE AND BORDERLAND CASES

ADOLF MEYER, M.D.
NEW YORK

The usual way to learn about diseases is to take up individual cases and to determine what specific matters stand out in the experiment of nature, and what special things shall be formulated into a plan of treatment or management.

When a whole field like that of psychiatry and its legal aspects in criminal cases is to be the starting point, one likes to take for granted a considerable experience with specific cases of the disorders to be subjected to such a special inquiry. But I do believe that even a general discussion of the general topic is bound to throw some light on how to become better acquainted with such a class of people as the insane.

At the very outset the problem appears rather different to the physician from what it appears to-day to the layman. The layman, and I am afraid most lawyers, consider insanity as a condition characterizing a more or less final subdivision of humanity, which is, or should be, fenced in by asylum walls. Asylum walls have indeed long been the most impressive and most intelligible definition of the whole group. Our text-books of mental diseases have up to recently been to a remarkable extent descriptions of what belongs in asylums, very careful of making their distinctions in the traditional terminology of mania, melancholia, paranoia and the terminal and senile and paralytic dementias. To make my first point as briefly as possible: Insanity is not a "disease" in the sense in which tuberculosis or leprosy are diseases, but it is a condition to which a number of totally different diseases may lead; some of them clearly mental disorders from the outset, mental defects, or poorly balanced mental habits miscarried to a point where the individual is no longer able to extricate himself, where he cannot be considered competent to manage his own affairs and to look out for his personal interests, not to speak of the altruistic demands. Some of these other diseases which may lead to insanity are more or less clearly the effect of poisons or of the undermining of the metabolism of the nervous system. Still others are diseases directly affecting the structure of the brain, through tumors, or injuries, or vascular disease or the like.

The nervous system is in one way a very enduring and hardy tissue; it loses least in states of emaciation, but it has little power of reconstruction if once organically damaged. This is the cause of the existence of the irrecoverable wrecks who no doubt form a class, requiring for life special care and protection against themselves and the encroachment by others.

But on the other hand functional disorders of a character most alarming to the uninformed are absolutely curable; the patients pass through periods in which they are not themselves, and then again reach a comparatively normal state in which they can hardly understand the abnormal actions ascribed to them. The fact that 20 to 25 per cent. of those who come to our state hospitals can be discharged recovered, and nearly as many fit for a protected home existence, shows that we are dealing not with a permanent class of individuals but with a group of diseases apt to present a common feature of more or less deep and more or less permanent disorder of conduct and behavior. The number of those who pass merely as nervous, but who have really the same disorders with less marked affection of conduct, is difficult to guess. From a medical point of view it is well to remember that the common saying that neurasthenics and hysterics and psychasthenics do not become insane, is a comforting tradition, but one not well borne out by experience, when these terms are used in a broad sense.

If we do not deal with a definite unit but with widely differing disorders, what is the common link that makes us speak not of "insanities" as we should, but of "insanity"?

They tend to make it necessary to interfere with the patient's own control and legal responsibility. They affect the patient's ability to regulate his conduct and behavior, and expose him and others to risks, perhaps only through the patient's "self-respect," or through his unwillingness to accept ordinary rules of hygiene and medical direction, refusal to rest, refusal of food, tendency toward self-mutilation or suicide, or aggressiveness and liability to disturbance of the peace, or actual violent assault. Or the patient may betray an unwarranted yielding to impulses, such as unchecked sexual yearnings, from merely platonic pursuit and insistence by letter to startling expressions of affection, proposals and attack, or a mere surrender to the opportunities of immoral houses; or the impulse leads to drink and its dangers; or to a wild and reckless spirit of expenditure, shown, for instance, by buying a dozen pairs of shoes, ordering a champagne bath in the Waldorf-Astoria, or ordering a piano each to a whole string of female friends; or inner emptiness and unrest combine to prompt kleptomania, or incendiarism. Or a husband says that his wife has either become a tantalizing fault-finding devil, making his life miserable by insinuations and scenes and complaints and inconsistent behavior, or she must be sick; it is a question which he cannot settle or put up with any longer; something must be done to control the aberration. Or the wife of a well-known ghost-hunter begins to take the spirit-warnings too seriously, beyond all reason, and creates embarrassing situations; he has to check her even against her remonstrations. Or note the attacks of terror in epilepsy, to the fright or suspicion in alcoholic delirium and states of persecution, and to all the strange and startling outbreaks of the fantastic dementia præcox. These are some of the innumerable difficulties the patients, or their friends, get into and the point is reached at which the former have to be checked. When the danger is acute and great as in a fever delirium, matters are not minced; the patient is unquestioningly left under the direction of the physician, taken to a hospital, kept there and if necessary, held in bed and subjected to the treatment and hospital rules without any discussion about the legal rights of the citizen. The citizen's first duty there is to submit to lawful order and best régime. In many other "insanities" the patients are just as unable to control themselves and to look out for themselves; they also remonstrate and resist; but in such a way as to appeal more connectedly to the fellow-citizen and to demand legal consideration. To take such patients to general hospitals is unsuitable, because they often do not do well there, are disturbing, often do not feel sick, and feel out of place. They need physicians and nurses trained to meet the peculiar demands, and perhaps merely a routine of orderly quiet life with occupation, and sufficient rest and protection against irritating influences. The only available places are the private sanitariums and our state institutions which serve as homes for the incurable and for the acutely disturbed and also for those in the protracted states of mental unbalance. To judge from contact with many trustees and visitors, these institutions are places really little known by the public; little known even by the authorities controlling these hospitals, and by the judges and the average physician and other persons likely to be appealed to for advice when the conduct of a patient becomes difficult to control. Outsiders repeat antiquated tales not much better than the gossip palmed off by the "antivivisectionists." The consequence has been a barbarous inconceivably stupid fence of laws around the institutions which alone are adequately equipped to bring timely or lasting help to the affected patients. The whole conspiracy of facts and imaginations and traditions has created a class of humanity under a special legal ban called forth for the protection of a few cantankerous individuals, where all that is necessary is the application of the quarantine principles, and provisions for legal reinforcement of medical persuasion and advice, or provisions for legal relief from unwarranted interference.

Nobody has a right to go where he pleases with diphtheria or small-pox. Nobody has a right to display himself in the street in a delirium. Nobody has a right to attempt or to commit suicide. The more we look on the matters as issues of health, the more do we accept even the impending danger as reason for action. We do not want to wait until a person exposed to small-pox breaks out all over, because he is a danger to the community before that. Even if a diphtheria-carrier has not diphtheria sores, he must be quarantined if he is the carrier of a virulent strain. In the mental cases much stronger evidence is asked for as a rule by those who do not know the seriousness of the conditions. Danger and threat of suicide can be foreseen by any experienced physician; but a judge may want evidence of unmistakable threats and attempts made. It actually looks more as if the field were ruled by the principles of criminal law with its provisions that nobody can be punished for a thing that has not been done.

We see then even in the case of non-criminals that the term "insane" is a high-water mark justifying the application of *some process of quarantine* or commitment. It applies to a stage or condition of many kinds of disorders which can exist without being destructive of safety or self-control, but are apt to involve the behavior so as to make protective measures necessary. Quarantine principles would be the ideal thing. Since the restriction applies to individuals who often do not submit to persuasion (as do most reasonable subjects of quarantine) but who object and fail to understand the situation, the right of legal appeal must, of course, be freely granted. It is decidedly an anomaly that has made legal decision obligatory for all admissions to a hospital even if there is not the slightest objection on the part of the patient or friends, or on the part of any one except the patient deprived of his own judgment—merely to do justice to the railroading yarns of the dime-novel type or to relieve the superintendent of responsibility.

By another anomaly the committing judge asks the testifying physician whether the patient is insane. To my mind it is the physician's business to state what the patient says and does and shows in the way of disease, and that the disorders thus reported prove him to be incompetent to direct his own case. It is the judge's privilege to declare that the patient's condition is that of insanity, while the physician uses whatever medical terminology he may favor, terms which hold good whether the case has reached the high-water mark of insanity or not, and which do not put a painful stamp on the patient and family.

Whenever we say that a patient is insane, we say no more than that he is sick, and that the disorder is one of the ways of disorder of conduct and behavior demanding certain special precautions of management and especially protection against his or her own warped judgment and impulses. The nature and condition of the disorder which is the physician's chief concern is immaterial to the judge, who cannot know it without study and thus has to keep alive a phantom-unit "insanity" and the notion of an insane class, instead of a roblem of quarantine.

We hear sometimes of a contrast of medical and legal definitions of insanity. This is an absurdity. "Insanity" is a term that I, as a physician, hardly ever use spontaneously. It is a practical designation for a practical situation and through our laws it has become a legally sanctioned term, while in psychopathology it has become a secondary issue. In some text-books there are peculiar strings of words called definitions of insanity. One of the simplest definitions demands that there should be protracted morbid deviation of the condition and conduct of the patient, such as incapacitates him to think, feel and act in relation to his environment in harmony with the standards of his bringing-up, and such as would entail a danger to himself and others.[1]

Law wisely abstains from any attempt at a definition of "insanity."

As a matter of fact it has several widely distinct standards and always according to the specific issue, namely:

1. Commitments.
2. Legal and testamentary competency.
3. Criminal responsibility.

The common link is the question of the existence of a mental disorder. The declaration of the legal status of insanity depends on special conditions for each of the three issues mentioned. The commitment, of course, is the most widely and fortunately most liberally applied category. As such it means nothing but "fit to be taken to a hospital against his consent." For certain contracts and even as a witness such a patient can still be competent, at least as much as a child between twelve and the age of majority, and in many points more. To take away the right of management of the property, requires an additional legal procedure.

With regard to testamentary capacity, the law has definite standards of a peculiarly broad character: the testator may be as insane as can be in any other sense as long as he knows the nature of the bounty and his natural responsibilities to his family, and the property-relations. Any delusions or disorders not involving these do not make the person incompetent.

With regard to crime the matter is not simple.

Many physicians think that a declaration of insanity is equivalent to a declaration of i [illegible] consequence of this assumption is [illegible] and begging the question. If one feels that one should say irresponsible, one says insane; if responsible, not insane. And yet afterward the excuse is urged that the person was irresponsible because of insanity; or the public may demand the execution of a Prendergast or a Guiteau, in the face of undeniable mental abnormality, so that evidently the issue must be different from that of mere mental disorder.

In this matter the written law is somewhat misleading. The pertinent paragraphs of the New York Code read as follows:

> § 20. Irresponsibility, etc., of idiots, lunatics, etc.
>
> An act done by a person who is an idiot, imbecile, lunatic or insane, is not a crime. A person cannot be tried, sentenced to any punishment or punished for a crime when he is in a state of idiocy, imbecility, lunacy or insanity so as to be incapable of understanding the proceeding or making his defense.
>
> § 21. Irresponsibility, etc., of idiots, lunatics, etc.
>
> A person is not excused from criminal liability as an idiot, imbecile, lunatic, or insane person, except upon proof that, at the time of committing the alleged criminal act, he was laboring under such a defect of reason as either
>
> 1. Not to know the nature and quality of the act he was doing; or,
> 2. Not to know that the act was wrong.

A similar see-saw appears in Section 22 in regard to intoxicated persons.

> No act committed by a person while in a state of voluntary intoxication, shall be deemed less criminal by reason of his having been in such condition. But whenever the actual existence of any particular purpose, motive or intent is a necessary element to constitute a particular species or degree of crime, the jury may take into consideration the fact that the accused was intoxicated at the time, in determining the purpose, motive or intent with which he committed the act.

In practice, physicians are inclined to appeal to Section 20 for simplicity's sake. The legal practice calls for the application of Section 21.

Another complication comes through the relation of the corollaries of a state of "insanity" to the punishment. When punishment is measured by responsibility and mental disorders reduce the responsibility, we come to the further inference that the perpetrator of an insane act shall go free. We shall discuss this monstrosity later.

Let us turn first to the criminal acts themselves. Crime is any act that subjects the doer to legal punishment. Without a specific law no act can be called a crime. Which of these acts occur among the insane?

---

[1] This is a good formulation for matters of commitment but too lax for those who assume that insanity should spell irresponsibility. The following definition of the issue in criminal cases was offered by Judge Barnes: "If at the time the crime was committed the defendant knew it was wrong to commit such a crime and had the power of mind to choose either to do or not to do the act and of controlling his conduct in accordance with such choice, then he ought to be held responsible, although he was not entirely or perfectly sane." This definition does not use the term insanity, which really becomes an undesirable complication.

In this description of how morbid disorders of conduct and behavior can influence action, I have already pointed out various ways that make the patient liable to misdemeanor. Looking over the mental disorders we see certain types predisposing to special types of crime.

The bulk of morbidly determined crimes is attributable to states of defective or uneven abnormal development, i. e., the various grades of imbecility, probably about 22 per cent. Certain forms of imbecility and defective balance are directly called moral insanity. Here we find thefts, forgery, swindling, sexual assaults and exhibitionism and other perversions, sexual murder, acts of revenge and spite, or mere impulse such as incendiarism. About 12 per cent. of the cases in Köppen's statistics belong to the paranoic group, much more likely to present distinctly aggressive impulses: murder and assault, disturbance of the peace in church or homes, insults, libel, threats and forgery or acts of revenge and sham defense. The simply paranoid forms of the deterioration-processes lumped together as dementia præcox shine with tramp-life, prostitution, exhibitionism, forgery, thefts and occasionally acts of revenge or sham-defense. The paralytic and senile become collectors, thieves, sexually aggressive, perjurers. Their occasional impulsive acts ally them with the epileptics, who present the most dangerous and brutal assaults, murder, rape, theft, and calumny; hysterics follow similar paths, alcoholics perform acts of revenge, and supposed self-defense, and at times epileptoid murders. Depression has led to family murder, a sort of vicarious suicide; or even murder committed for the sake of a passive suicide by execution, and other abnormal ways of breaking through the morbid feeling of tension and restraint. Manic excitements prompt to transgressions and excesses, especially in sexual matters, or vituperation or violence.

The question arises: are there any crimes which are clearly the act of an insane person? Concerning this point I should be cautious. Some of the crimes are so blind and violent that they exclude all cool consideration. But this may hold for any acts of passion. If a murder is well planned and well covered up, or if the delinquent acts normally and with perfect coolness, the act may still be the clear result of an abnormal mental state. It is by far the best rule to claim that no crime or act as such can be estimated properly without a study in the light of other acts and tendencies and the general reaction and complete record of the person.

The practical side of the question of the criminal insane is to determine not so much what crimes occur among the insane as what shall be done about certain crimes in which the issue of insanity is raised, and what the aims are of the criminologist and the judges in their decisions. I assume that the aims are: (1) to ascertain the facts; (2) to determine the guilt; (3) to assign the punishment or judicial remedy; (4) to bring about the effects expected from punishment. As to the determination of guilt, we seem to have a three-cornered interdependence between responsibility, guilt and punishment. The only safe statement is, I suppose, that responsibility is liability to punishment. We might make that mean that every defendant exercised a certain amount of choice to do better or worse. The lesson which the punishment should teach him and others is that he should have chosen the better course and that, not having chosen it, he has made himself liable to that punishment. It is further supposed that it is his duty as a citizen to know that lesson and that he cannot be excused for not knowing it. Irresponsibility through insanity would, I suppose, only apply if on account of mental defect he never could have learned this, or even with this helpful experience or knowledge, he would not have been able not only to choose the better, but really to know his moral lesson. The whole question of guilt is forced to operate with a hypothetical argument because it presumes an answer to the question whether his condition did allow or might have allowed him to know certain things and to make the proper use of what he did not use or choose. It is the theory of the intent that looms up. However that be, it certainly is best to leave out of discussion the question of free will and determinism which divides the camps in Germany. Practical will and practical determinability is all that concerns us. We need not prejudge the universe by a doctrine.

But now how about punishment? It is after all more than retaliation or correction. Our aim is also prevention and protection of society. In this direction jurisprudence cannot remain behind medicine very long. Its rule is, of course, that the individual shall not be punished for acts not committed. We cannot well speak of punishment for mere intentions. Yet we must correct intention. And those intentions which lie as it were in the flesh and blood of a constitution long before they are conscious, call for some measures, if the protection of society demands it. Social quarantine is the only hope for the future. Actual detention of antisocial elements and the prevention of their propagation are as much or much more our duty than is the quarantine of the leper and of Typhoid Mary and the temporary quarantine of the carrier of small-pox. Punishment which does not prevent is insult added to injury. The question thus should arise in every case and it should be addressed to the competent expert or a commission of experts: Should the mental disorder or condition found modify the punishment, or to speak more exactly, the disposal of the case? Is the person fit to undergo the ordinary course of justice? Will he be improved by it? Will he need other measures for prevention than the punishment which law considers a good enough method for the average? On this score I should like to say most emphatically that medical jurisprudence has made egregious blunders. It has been sentimentality-mad or the victim of verbal logic. Infinitely less harm would come from making the sick man take the consequences of his liability to such sickness just as we put a man liable to small-pox under quarantine, instead of letting free a lot of unworthies and raising an appetite for the plea of insanity to a point with exhibits which nauseate every sober-minded citizen. Physicians do not care to be the vaulting pole for escape from natural and proper consequences of a person's nature. It is true we want decent places for the persons detained, chances for a decent and profitable life. Men like Forel have long written and spoken for special colonies for special types of cases. My own feeling is that if we get decent prisons run as they ought to be, many persons now sent to asylums for criminals or let loose had better be sent to prison unless it can be shown that actual harm to their mental health would come from it.

Punishment was and is a means of correction in normal education. This has changed much during the past two generations. There has probably been too much of a reaction from the life of puritan duty. Laws would mean more if we could keep them stern and firm. Among the insane we have abolished the word and thought of punishment. But we have the responsibilities for discipline. We want to make our patients as responsible as possible and it is mainly our task to protect them from spheres in which they would flounder helplessly. If you abhor the conception of relative or partial responsibility, I should stand up for the principle that there is no absolute irresponsibility even among the insane and that it is much better to deal with them from case to case for what there is sane in them, not with the principle of retaliation, but by placing them with a clear understanding just where they belong, according to their make-up and temporary condition. Where mental disorder is demonstrated, none but the principles of equity will wear well. Can they ever be looked forward to here? They would be as little cherished by the real criminal as the indeterminate sentence is liked by the professional; but every fair-minded victim would fare better than with our present way of using legal rules. A common-sense consideration of the facts of conduct and behavior is in order, if possible to avoid that the victim really becomes dangerous and is allowed to perpetuate the poor stock of our race. What a preposterous condition when juries have merely the alternative between the electric chair and acquittal! This is where help is needed and an introduction of equity-principles might justify preventive considerations.

We may be a long way from special colonies. Certain individuals can be employed *near* institutions, if they are too well to be kept there and too dangerous to go wholly free. And others should at least be asexualized—a point on which I hope more of our citizens will in time agree with us when enough evidence is at hand to convince open-minded opponents.

To look back one moment: The law must give us more clearness as to what it wants. It must be ready to deal with disease according to the principles of disease, and therefore realize the necessity of equity principles (rather than the "rules of the game" of evidence in a fight about liberty) and the necessity of consulting the expert not only concerning the indefinable term "responsibility," but also the effect of the special condition on the preventive steps required.

How, now, about the physician in a concrete case? In a genuine and unmistakable case of mental disorder in which an accident otherwise amounting to a crime failed to be prevented, the perpetrator will, according to our present practice, be taken to a jail, but probably be seen by a physician, if not taken immediately to the proper reception hospital, if one exists.

In almost all the *questionable* cases no move was made to get a competent and trained physician until the question of a "plea of insanity" arose. It should always be a suspicious sign if no move is made equivalent to the examination of the patient for a commitment as soon as possible after the act. Where the defense of the criminal is the main thing and insanity the only means of saving him from the consequence of his act, the procedure is usually from the start a perversion of psychiatry. Physicians are called as partisans; examinations must be made under the most unpropitious circumstances. There is no official impartial record kept such as we demand in a well-conducted hospital to-day; there are no trained attendants employed. As soon as the authorities have reason to suspect a mere suspicion of insanity, or of a plea of insanity, the immediate attention of a trained physician should be called; and to be on the safe side every prison physician should have training and experience in psychiatry. He should make a full examination with a satisfactory record and should have the proper type of attendants for the examined prisoner. During the whole stay of the prisoner or suspect the written record of the physician should be kept up, consisting of statements of what the prisoner said, did, and showed on medical examination. Where the condition is doubtful, some states can send the prisoner to a hospital for observation for a maximum period of six weeks. In making an examination for one side or the other the only way to proceed is to come as near as possible to the plan mentioned. Under well-regulated conditions the competent hospital men of the district should do the work for the state as state officials and they should have the right to apply for a period of hospital observation of the patient and always the duty to furnish a written report. The alienists of the defendant would naturally and automatically be guided by the standards of the official physicians.

Now the physician's share in the determination of guilt! The physician's duty above all things is to determine and report the existence of any mental defect or disorder at the time of examination and in the record of the past. This should consist in the simplest possible terms of what the patient did and said and showed medically, rather than a mere learned treatise on the diagnosis and symptoms which should be reserved for the summing up of the written record, if one can be demanded.

If there are no plain facts sufficiently convincing to form a demonstration of an abnormal trend, learned terms will only confuse. The aim should be to show that, in other situations and actions, an abnormality was present, and that it played a definite rôle in the determination of the act under legal consideration. To avoid ambiguity, the term "insane" and "insanity" should be replaced by "mental disorder," specified by its effects in various actions, including or not the act *sub judice*. In this, Mercier insists on a psychologic analysis of the acts. I agree to this only as long as we move on objective ground. The main question is that of intent. Therefore the relation of the existing disorder to the intent must be defined, and here comes the chief point at issue.

Unfortunately the rôle of the physician is at this point involved in an issue which I think should not be looked on as a medical question. If the physician has to say "yes" or "no" to the questions: Do you consider the patient "responsible"? and Do you consider the patient "insane"? he becomes part of the jury or in the absence of a jury expresses himself in a judiciary capacity. Neither responsibility nor insanity are medically useful or even admissible terms. The physician must make it clear that there is a mental disorder and that it had or had not a bearing on the act and, as far as possible, the evidence by which he can prove it. But the rest is a judicial interpretation gratuitously offered by a physician at the risk of being turned down by a jury or a judge who knows more of the law than the doctor, and, at the same time, appears to decide a medical question for him. I do not want to jeopardize the rest of my propositions by insisting too much on this subordinate point, however. I favor it because physicians are too well trained in their business and science to believe themselves able to give always an out-and-out positive or negative reply to a question to which they know science and plain fact can give only a conditional reply. Legal practice opposes the concepts of relative or diminished responsibility and for this the plain man or layman can be had more readily than a man who must aim to keep toward the scientific attitude.

In each case in which a mental disorder is demonstrated, no matter whether it figures as insanity or not, the alternatives of allotment of punishment should be put before the expert for a statement as to the probable effect on the success of the aim of punishment or the effect on the disorder and the needs of protection of society.

Much has been said, and with sad justification, of corrupt medical testimony. It is one of the most disheartening displays of the low standards of our general and business morality. When nobody steps forward to slap the one who can say with impunity: "Every man has his price," we have to hear it until it becomes an accepted standard. And if the professional expert works for his client, what does he do? Ninety times out of a hundred his worst crime is that he assumes what he calls the lawyer's attitude. Where are the legal standards of the great masters? Why do we not ostracize a man who sacrifices the facts and his better knowledge to the undeserved success of his client? This is a matter of public standards of business morality and of morality within the professions. The scandal I am afraid is a symptom of our kind of general ethics. I do not know how the legal profession will check the doings of some of its most successful agents of perversion of fact. We physicians are trying to make some of the men accountable for their statements. But they invariably put the blame on the legal methods, the questions asked and the like.

For this reason I urge a wider use of the *written reports* of the observations and conclusions made by the medical expert which exclude the gambling of the questionaire without in any way excluding the most searching cross-examination. Most cases are simple and cause little trouble. But the cases which give trouble are just the ones in which a man who poses as expert should make a statement for which he makes himself wholly and unmistakably responsible, without any excuse or subterfuge. German expert testimony has its high standards through no other one tangible thing but this accessibility of written and responsible documents.

In trying to prepare this paper I deplored the absence of digests of the practice of our courts. When will the judiciary and legal world introduce research as an obligatory condition of a career of a teacher and put the young elements to work to keep up a system of monographs and digests and to make inquiries into groups of concrete cases and their specific difficulties and demands, rather than dialectic dissertations? The consideration of concrete cases as practical experiments alone will bring order into the bewildering chaos.

My theses are:

1. The solution of the medicolegal problem of mental disorders generally lies in a further development of the quarantine principle, medically and legally.

2. In handling the criminals presenting mental disorder, jurisprudence will have to develop rules of preventive care beside the rules concerning acts already committed.

3. To avoid begging the question, and confusion of definitions, the question of the bearing of mental disorder should not be settled under the heading of guilt only. Insanity and irresponsibility are not coextensive and should not be made so and are not safe terms medically and legally. Therefore, the procedure should cover:

A. The fact of commitment of the act.

B. The existence of mental disorder at the time and its bearing on the act.

C. The bearing of any existing mental disorder or tendency on the legal consequences of the act, the punishment, the prevention of similar acts, etc. In every case with mental disorder it should be obligatory to ask: What is the relation of the mental disorder to the act? and what does the mental disorder demand to make the punishment and correction and further prevention efficient?

4. In order to meet the problem of partial responsibility and crimes of passion, the law should create better alternatives than the unwritten law, and in cases of mental disorder, the equity procedure should be substituted for an unconditional declaration of not guilty.

5. I strongly suggest the requirement of written statements of facts and opinions by the experts employed as the only means of establishing standards.

THE PHARMACOLOGY OF IODIN AND THE IODIDS*

J. H. SALISBURY, M.D.
CHICAGO

A satisfactory explanation for the action of medicines can be found only in a consideration of their chemical relations since drugs can act only by producing chemical changes. In the case of iodin the interrelation between its chemical properties and its physiologic action ought to be found quite readily, since it is an element and its chemical characteristics are well understood. A difficulty arises, however, in discussing the relations of any drug, from the fact that the animal system on which it acts exhibits such a complexity of chemical changes that we cannot adequately explain the effects of even the simplest element on it. Nevertheless it will be worth while to review briefly the more marked chemical properties of iodin to see how far we can go on the road to a rational explanation of its pharmacologic and therapeutic action. This element is remarkable, in the haloid group, for the comparative weakness of its chemical affinities and the ease with which it is freed from its compounds. In consequence of this property it is easily displaced from its combinations by oxygen, chlorin, and bromin. Hydrogen iodid or hydriodic acid is especially unstable. Iodin shows a tendency to form peculiar double salts, such as the combination with potassium iodid, giving the hypothetical compound, KI_3, and the double salts with mercury, such as potassium mercuric iodid, $2KI, HgI_2$, or K_2HgI_4. The readiness with which it becomes free is shown in the well-known incompatibility between potassium iodid and ferric chlorid, in which case ferrous iodid is formed instead of ferric and a portion of the iodin assumes the free state. This reaction is largely due to the fact that ferric salts are capable of reverting to the ferrous condition and *vice versa*, but it must be remembered that quite similar changes are constantly occurring in the animal organism. Another property of iodin which must be of physiologic importance is its tendency to combine with fats and fatty acids. Similar reactions occur with alkaloids, with which it forms insoluble compounds, and with proteins, into the composition of which it enters to form new compounds and in many cases to displace the corresponding chlorin ion. The iodo-organic compounds are comparatively stable and inactive and it is chiefly as the result of oxidation that the iodin again becomes liberated. One of the most important organic compounds of iodin is the globulin found in the thyroid gland, which undoubtedly plays an important rôle in the metabolic processes of the normal body. This substance has its analogues in other parts of the organism and it is believed that no living cell is entirely devoid of its organic iodin compound.

---

* Read at a meeting of the Evanston and North Shore Pharmacologic Society, at Evanston, Ill., April 14, 1910.

When we consider the unstable nature of its compounds and its readiness to enter into all sorts of compounds it is easy to see what a disturbing element free iodin must be in the animal economy. It may readily be compared to fire, which, useful, when under control; for the warmth which it affords, is to be dreaded when it is allowed to exert its destructive action unrestrained. That the system is able to use this agent in ordinary metabolism is undoubtedly due to the fact that the protein combination in which it is deposited in the thyroid is so slowly decomposed that its destructive action is just enough to secure the physiologic changes necessary for the removal of waste and for the control of nutrition. When for any reason this control is lost we see in the phenomena of hyperthyroidism the manifestation of a mild form of iodin poisoning.

From its chemical nature iodin can exist only for a short time in the animal system in a free state and when absorbed iodin is changed to an iodid or to a protein compound so that the internal actions of iodin are practically identical with those of the iodids and are to be considered with them. It is, not to be forgotten, however, that the iodids are readily decomposable with the liberation of iodin so that it is probable that the action of iodids on the cells and fluids of the body includes the temporary action of free iodin to a limited extent in their ordinary activity and to a much greater extent in circumstances in which this action amounts to that of a toxic agent.

The iodids are mainly very soluble, easily dialyzable, easily ionizable salts. These properties are responsible for much of their pharmacologic and therapeutic action. The easy solubility makes it possible for the organism to dispose of such amounts as are not easily combined with protein by elimination through the various emunctories. Thus, according to H. C. Wood,[1] John Marshall recovered 265 grains daily from the urine, in a patient under his care who was receiving 360 grains of potassium iodid daily. The dialyzable character of these salts enables them to enter cells readily but when within the cell they have combined with protein molecules they become colloids that will not dialyze out again until they have been changed to the crystalloid condition. Their ionizable character makes them ready to enter into double decompositions that disturb the chemical relations of the other conditions of the cell and alter the character of the cell plasma. Particularly the iodid ion tends to displace the chlorid ion and to cause its extrusion from the cell probably in combination with the potassium ion which is usually the metal introduced in combination with iodin.

With this brief discussion of the chemical relations of iodin we are prepared to enter on a consideration of the pharmacology of this element and its salts. We shall consider first the local action of iodin and second the action of iodids and the constitutional action of iodin.

LOCAL ACTION OF IODIN

Iodin is essentially an irritant which destroys the cell, combining with its protein constituents and provoking a reactive inflammation on the part of tissues less violently affected. The affinity of iodin for the protoplasm of the cell is seen when vegetable cells are stained with Lugol's solution. The protoplasm receives a marked yellow stain indicating that the iodin has penetrated the cell and entered into combination with its protein constituents. The experiments of Lillie[2] on unfertilized *Arbacia* eggs indicate that, next to cyanids, the iodids of potassium and sodium have the greatest power of increasing the permeability of the plasma membrane and that they thus make possible the loss of the cell constitutents, instituting a series of changes which eventuate in the death of the cell. The destructive action of the element on the lower forms of life constitutes it a good disinfectant. Its value in the treatment of many skin diseases is largely owing to its disinfecting action. Iodin appears to be somewhat astringent, drying and puckering the tissues to which it is applied. The irritation of the deeper tissues develops, somewhat slowly, inflammatory changes which result in throwing off cells destroyed by the iodin and replacing them by new formed tissue. Iodin applied to wounded surfaces and to ulcers acts as an efficient disinfectant and promotes the subsequent healing of the underlying surface. Goebel[3] found a diluted Lugol's solution (iodin, 5 parts, potassium iodid, 10 parts, distilled water, 250 parts) an efficient disinfecting fluid for surgical use. The value of iodin in surgery has been the subject of several recent communications showing a renewed appreciation of an old and well-known remedy.

On mucous membranes the action of iodin is quite superficial, and especially when applied to the gums its destructive action is so limited that it forms one of the best applications for gingivitis. Especially in the treatment of interstitial gingivitis, the so-called pyorrhea alveolaris, it has proved to be one of the best of remedies. Its action on other mucous membranes is similar and the good results obtained from its use are easily explained by its disinfectant action, its destruction of tissue, particularly that of low vitality, and the stimulation of healthy tissue to regenerative action. The hyperemia induced by such stimulation plays a very similar part to the hyperemia induced by the method of Bier in the treatment of inflammation and infection.

INTERNAL ACTION OF IODIN

When absorbed into the blood iodin necessarily enters into combination so as to form iodids or possibly combinations with protein material. Its solution in the akaline media of the blood and lymph can be effected only with the formation of some oxidized form of iodin, such as iodates or perhaps a transient occurrence of the lower acids, which we know are very unstable. The action of iodin in its free state cannot, therefore, be quite equivalent to the action of the iodids since it involves the action of these unstable compounds which must have a destructive action corresponding to their instability. Iodin is not absorbed to a perceptible extent from the sound skin but from raw surfaces, wounds, and mucous membranes it may be readily taken up so that it may be demonstrated in the urine and may even produce symptoms of poisoning. In some forms absorption may take place through the skin. Thus Kellermann[4] by inunction with iothion found that from 8 to 18 per cent. of the iodin was absorbed by the skin and excreted in the urine. Himmelsheber[5] attributes the occurrence of acute hyperthyroidism following operation for prolapsus uteri to the absorption of iodin from iodized catgut sutures.

[3] Goebel: Centralbl. f. Bakteriol., 1906, xliii, 86.

The symptoms of iodin poisoning are throughout characterized by their irritant character. According as the irritation is produced on the mucous membrane of the gastro-intestinal tract, the internal organs, the respiratory mucous membrane, or the skin, various types of reaction are produced and these types are worthy of special study as they may point the way to therapeutic applications.

Large doses of iodin are irritating to the stomach and may produce gastritis. Suppurative gastritis has been attributed to the action of iodin, it being supposed that iodin produced a pustular eruption in the stomach similar to that sometimes occurring on the skin under its influence. From experiments on dogs with Pawlow's miniature stomach, A. Bickel[6] found that iodin and potassium iodid increased the amount of gastric juice, thus tending to produce hyperacidity. This was followed by an increased secretion of mucus, so that these agents, like alcohol and other irritants, are capable of producing a gastritis having the characters of acid gastritis. A similar action was produced by an albuminous compound containing iodin. Bickel proposes to use this experimental production of gastritis as a test to determine whether a preparation contains iodin in a therapeutically active form. If such a compound increases the acid and mucus of the stomach experimentally it may be assumed that it will exhibit the therapeutic properties of iodids in the organism.

Colic and diarrhea are frequent symptoms of acute iodin poisoning. Vomiting may occur. The inflammation of the gastro-intestinal tract is seldom severe, and if it is not, large doses do slight harm. In spite of the active symptoms produced, iodin poisoning is seldom fatal. This result is averted by the conversion of the element into compounds which are non-irritating and readily eliminated. In cases in which absorption has already taken place the gastric and intestinal symptoms of iodism are usually lacking or very slight. In small doses suitably diluted the gastro-intestinal irritation is not noticeable, and the remedy is often used for symptoms of irritation of the stomach, such as vomiting, gastralgia, etc. It has been prescribed along with phenol for the treatment of typhoid fever, probably on the supposition that it would exert an antiseptic action, but such an action in the alkaline contents of the intestine is very unlikely, if not impossible.

The action of iodin on the internal organs is also that of an irritant and when marked is shown by rapid pulse, flushing of the surface, increase of temperature, tremor, dizziness, and general weakness. Iodin introduced into the circulation takes the form of an iodid or of an organic iodin compound. It is removed from the circulation by the cells in general and especially by the cells of the thyroid gland. The varying capacity of the cells to take up iodin leads to a varying distribution of the element in the various tissues. The amount deposited depends not only on the character of the tissue, but also on the nature of the compound in which the iodin is introduced.

Labbé, Lortat-Jacob, and Boulaire[7] conclude, from experiments to determine the coefficient of accumulation of iodin in the various organs, that the element has a great affinity for lymphoid tissue. It was deposited most abundantly in the spleen and lymph glands and next in the liver, which contains lymphoid tissue. Iodin, iodids and iothion cause the greatest accumulation in the lymphoid tissue while the fatty compounds leave very little. Loeb found the brain, spinal cord, bones, and fat free from iodin after the administration of potassium iodid, but found in the blood and liver, after removal of soluble iodin, a small quantity which was probably in the form of an organic compound. When iodoform, iodanilin, and ethyl iodid were administered, a considerable amount of iodin was found in the fatty tissue. It would seem that the presence of the iodin in an organic combination makes it possible for certain tissues to absorb it that cannot take it from the inorganic forms.

In the thyroid iodin is stored in the form of a colloid, not in the cell, but in the intercellular spaces. That the amount of iodin which can be stored in the thyroid is greater than that which is taken up by other organs is well demonstrated. This is not accounted for by the colloid character of the thyroid secretion, for other colloids, like that of the hypophysis or pituitary gland, do not contain an especial amount of iodin. The thyroid appears to act as a detoxicating organ to remove irritating poisons from the blood and to store them in its tissues. That the substance removed is not always iodin appears from the fact the colloid is frequently secreted by the thyroid cells without containing any iodin. In these cases it may be that the gland has removed other irritating substances by combining them with the colloid and storing them in the intercellular spaces. However, this may be, the removal of iodin from the circulation by this means is a most interesting phenomenon. If we look on this production of iodin-containing colloid by the thyroid as a detoxicating process, it will be readily understood that marked effects from the ingestion of iodin occur only when the iodin is present in the blood in such quantity that the thyroid cannot remove it fast enough to prevent toxic effects or when the thyroid has already exhausted itself in the production of colloid and small quantities of iodid pass constantly into the blood either from the colloid secretion stored up in the thyroid or from other sources. The colloid, once deposited, appears to remain until it is taken up by the same cells which produced it and returned to the blood. Experiments by Carlson[8] show that the colloid is not taken up by the lymph which contains no iodin. When this introduction of iodin from the colloid into the blood takes place in normal amounts it may perform a useful function in metabolism; if the amount thus set free is excessive, symptoms of iodism appear which seem to be identical with hyperthyroidism. Whether the iodin produces these effects as an organic compound with protein or whether a decomposition of the protein must first take place so that the iodin becomes free or, at least ionic, is not determined.

That iodin released from the thyroid proteid may act as an immunizer against other poisons is shown by the experiments of Reid Hunt[9] with acetonitrile. This observer found that mice treated with thyroid extract containing iodin would survive a dose of aceto-nitrile from one-half to twice larger than that which was fatal to control mice. The protective power was shown to be nearly proportional to the iodin content of the thyroid extract. Hunt also found that iodids and other compounds of iodin afforded a similar protection, although not to the same degree. It is probable, therefore, that iodin plays an important rôle in the control of nutrition and metabolism by the thyroid gland and that the gland may act both as a moderator and as a stimulant of metabolic activities, according as it removes iodin or other irritants from the blood and stores them in its tissues, or returns them to the blood when needed. Iodin is eliminated by various emunctories, among which the kidneys are of prime importance. The elimination through the kidneys may lead to such irritation of these organs that a nephritis may be set up, which contributes in no small measure to the injurious effects and rare fatal issue of iodin poisoning.

Elimination by the respiratory tract gives rise to some of the most characteristic symptoms of iodism. Salivation is a common symptom. Coryza and more serious inflammation of the nasal mucous membrane may ensue. The irritation of the bronchial mucosa may lead to hoarseness, cough, asthmatic symptoms, etc. These forms of respiratory irritation are easily elicited by the iodids when they produce no especial general or gastro-intestinal symptoms, because on the surface of the respiratory mucosa decomposition with liberation of free iodin most readily occurs. The increase of secretion in the bronchi under the influence of iodids has been made use of as a diagnostic measure to secure the presence of tubercle bacilli in the sputum or by causing the production of râles in the neighborhood of tuberculous foci to facilitate their recognition by auscultation.

Irritation of the skin results in the production of various eruptions such as erythema, acne, bullæ, which may suppurate, and ulcerations. The acne of iodism is likely to result in pustules which may be quite troublesome. The acne has been attributed to a derangement of the circulation in the superficial areas of the skin. F. Schidachi[10] reports 5 cases of erythema nodosum from the use of iodids and discusses some interesting questions in this connection. The suggestion that such eruptions are connected with kidney lesions received no confirmation from these cases, as albuminuria occurred in only one case. The theory that the eruption was due to imperfect elimination of the iodid could not be maintained as quantitative determinations of the iodin excreted showed that the intensity of the eruption did not in any way correspond to a lessened elimination by the kidneys. The lesion seemed to be due to a disturbance of the circulation similar to that supposed to cause acne, but affecting the deep instead of the superficial blood-vessels. Why there should be a difference in the vessels affected in various cases is not explained.

PHYSIOLOGIC ACTION OF THE IODIDS

The iodids are, as has been said, mostly soluble, dialyzable, and easily ionizable salts which are eminently fitted to produce a slow but profound effect on the changes going on in the cells. Under their influence cells waste and the more lowly organized the tissue, the more readily is it affected, so that fibrous tissue is especially likely to be softened and removed during the action of the iodids. In their internal activity the iodids repeat the actions of free iodin, causing the symptoms of iodism when they are administered in large doses. Their rapid elimination and the probable transformation into a colloid form prevent a marked development of this action so that the acute manifestations of iodism are seldom noticed in the administration of the iodids and then usually only for a short time. Iodids give important assistance in the elimination of metallic poisons, particularly lead, mercury, and arsenic. The explanation of this action is not positively known. It is believed that the iodid acts by producing a soluble salt of the metal, but it seems quite as likely that the iodid may release the metals by breaking up proteid compounds which they may have formed. A similar action may explain the increase of elimination of toxins under their influence.

The action of iodids on the circulation has been much studied but it is not certain whether they possess any marked action on the arterioles or not. It has been claimed that they lower blood-pressure, but some of the experiments seem to indicate that the first effect is that of an irritant to the vessel walls, causing contraction of the arterioles and a consequent temporary rise of blood-pressure, and that they develop their influence in lowering blood-pressure only by their action on the fibrous tissue of the blood-vessels, by which they diminish arteriosclerosis and eventually lessen arterial tension. However a lowered arterial tension is a prominent feature of hyperthyroidism and would seem to indicate a similar action on the part of the iodids.

Loeb[11] found that the use of iodin preparations by injection did not hinder the degeneration of the aorta produced in rabbits by injections of adrenalin, but very large doses increased the extent of the lesion. On the other hand, Martinet[12] attributes the good effect of iodids on arteriosclerosis to three factors: 1. They lessen arterial tension to a certain extent and relieve the heart. 2. They act as lymphagogues; they lessen edema although at first they increase it. 3. They are useful by their action on nutrition.

Iodids are useful in asthma, but the mechanism of this action is unknown. They are good expectorants because being excreted by the bronchial mucous membrane, they tend to liquefy secretions and to promote the expulsion of the sputum. A similar explanation will suffice for their favorable action in coryza and nasal catarrh.

IODISM

The occurrence of iodism during the administration of iodids suggests the following important questions: 1. To what is iodism due? 2. What circumstances favor its onset? 3. Is iodism necessary to the therapeutic action of iodids?

According to A. Djelogolowy[13] iodism is an iodin intoxication which may have more than one cause and is to be attributed to the setting free of nascent iodin by the action of some oxidizing agent on the iodids. This oxidation may take place in the stomach or after absorption into the blood or after the iodid is eliminated on a surface exposed to the air like the respiratory mucous membrane. Djelogolowy concludes that in certain individuals the conditions in the stomach are especially favorable to the spitting off of free iodin and the production of an iodin intoxication. In these individuals the acidity of the gastric juice is high and the stomach contents contain nitrous acid produced from nitrites derived from the saliva or from the food. The nitrous acid sets free iodin from iodids when given as medicine. This theory affords a useful hint as to the giving of iodids, viz., to give with them something to neutralize the excess of acid in the stomach. The ordinary precaution to administer them in milk is seen, therefore, to be based on sound principles. The protein of the milk tends to neutralize the excess of acid in the stomach and thus to prevent the action of nitrites on the iodid. Probably the administration of alkalies would afford a like security. Djelogolowy finds that the amount of nitrites in the stomach contents varies with the abnormal secretion relations. On the amount of nitrites depends the amount of iodin split off and to a corresponding extent the sensitiveness of the patient to iodin preparations. The setting free of iodin and the presence of nitrites are constant symptoms presented by the patient in whom they are found, for they are always found on repeated examinations with unimportant variations.

[13] Djelogolowy, A.: Arch. f. Verdauungskr., x, No. 3.

Not less important in this connection are the views promulgated by Erlenmeyer and Stern,[14] who, in discussing the use of iodin in arteriosclerosis, conclude that iodism is a necessary accompaniment of the therapeutic action of the iodids. They regard the action of iodin as essentially the action of the iodid ion, and hence think that it cannot be exhibited unless the iodin is in the ionic form. It can be obtained only from such preparations of iodin as dissociate in the system. Of these the iodids of the alkali metals are the most powerful. Iodism is an unavoidable side-action of the activity of the iodid ion. Its intensity is to be moderated, but the occurrence of iodism is neither to be dreaded nor to be entirely suppressed by antagonistic agents. If the views of these authors are correct, the administration of iodids should be conducted with the definite aim of developing a mild form of iodism with as small doses as possible. In the opinion of Erlenmeyer and Stern organic compounds of iodin are therapeutically efficient only on condition of their splitting off iodin in the body so that such compounds can be only somewhat uncertain substitutes for potassium or sodium iodid. If we can guard the stomach from the injurious action of iodin it would seem that potassium iodid is still the best salt to develop the therapeutic activities of iodin.

While we must leave a number of theoretical questions unsolved the preceding discussion suggests the following practical problems worthy the attention of clinicians and pharmacists. Since the liberation of iodin appears to be the cause of the untoward effects of iodin and the iodids what means can be taken to avoid this occurrence or to restrain it within moderate limits? This is a problem to the solution of which the knowledge of the pharmacist may bring valuable aid.

Again what is the proper treatment of this condition when once produced? In answering this question pharmacy and toxicology should come to the aid of practical medicine.

Lastly, if this condition in a mild degree is the indispensable condition of therapeutic efficacy from the iodids, pharmacologists ought to find some way to evoke it in the system without allowing it to go too far and should teach us how to avoid the injurious action of the remedy on the gastro-intestinal tract and the excretory organs.

I shall not attempt to discuss these questions, but will leave them to the reader in the hope that some substantial contribution to their solution may be presented.

THE EXPERIMENTAL PRODUCTION OF SECONDARY UNION BETWEEN NORMAL AND CARCINOMATOUS EPITHELIUM—PSEUDO-METAPLASIA*

PEYTON ROUS, M.D.
NEW YORK

In the never-ceasing discussion on the origin of cancer, much attention has always been given to that continuity between normal and carcinomatous epithelium which is so frequently observed at the edges of tumors. Many pathologists hold that the transition here noted is evidence at once of the primary seat of the growth and of its manner of origin. Certainly this evidence would seem strong, and those who do not accept it are few. Ribbert has long held that a secondary union really explains such pictures, and Borrman,[1] his pupil, has collected many specimens which histologically further this view. Experimental evidence for it, however, has been lacking.

In the course of a comparison of the conditions regulating the growth of transplanted tumor and a transplanted normal tissue[2] I have examined many grafts in which mixed tumor and embryonic tissue have grown intimately together in the new host. A few of these have shown microscopically an undoubted union between the carcinomatous and the embryonic epithelium, especially that of the skin (which, on its growth in the new host, tends to assume the mature form). Mouse tumor, adenomatous or alveolar in character, and hashed mouse embryos, 1.0 to 1.6 cm. in length, have been used. The tumor is easily recognizable in such a mixed graft. The union of it with the normal epithelium is seen most often where tongues of the two, growing in opposite directions along a rift in the injected mass, have met. In some cases a real fusion does not take place, and where the tissues have come in contact they remain sharply distinguishable, although no fribril or free space separates them. In other instances there occurs such an intermingling of cells at the meeting-point that with the microscope it is impossible to determine exactly where normal epithelium ceases and carcinomatous begins. Indeed, on histologic evidence alone, it would be said that here was a metaplasia. The possibility that in these instances one may be dealing, not with tumor tissue at all, but with a junction between skin and skin appendages, can be excluded.

The fact thus experimentally brought out that normal and carcinomatous epithelium may secondarily unite probably explains only a part of the recorded cases in which a continuity between the two has been observed. It does not prove that such a continuity may not often be primary. But it should lead to more caution in the acceptance of pictures at the edge of a growth as evidence for the growth's point of origin, or for its having arisen by a metaplasia. At the edge of an ulcerating epithelioma, for example, where the skin epithelium is making attempt at repair, and the tumor tissue is extending toward it, there must occur many opportunities for a secondary fusion of the two, such as has been here reported.

THE EXCRETION OF HEXAMETHYLENAMIN IN THE SALIVA*

PAUL J. HANZLIK
CLEVELAND, OHIO

The excretion of hexamethylenamin in the urine was reported by Nicolaier[1] in 1899. The favorable results obtained from its use as a urinary antiseptic created an interest in its mode of excretion by other channels. Crowe[2] has reported its excretion in the bile, pancreatic juice, cerebrospinal fluid, synovial fluid, and in the saliva and milk of dogs, and has used the drug as a prophylactic and therapeutic agent in meningitis, but particularly in gall-bladder disease due to gall-stones complicated with *Bacillus typhosus*. The excretion of hexamethylenamin in human milk has also been observed.[3]

Recently W. M. Barton[4] and E. J. Brown[5] have reported the use of hexamethylenamin in the treatment of otitis media and suppuration of the right antrum. The possibilities of treatment of meningitis complicated with otitis media and infections of the sinuses were suggested in Crowe's work. In Barton's case the excretion of the hexamethylenamin by the mucous membrane was shown by the chemical test. In Brown's cases no attempt was made to detect the appearance of the drug in the secretions.

The mode of excretion of hexamethylenamin as such or as formaldehyd plays an important part in the estimation of its value as an antiseptic. In the urine it has been observed that at least a part of it appears as formaldehyd if the urine is not voided too frequently. Sollmann[6] has shown that a considerable part (if not all) of hexamethylenamin is excreted unchanged in the urine, but when the urine was retained in the bladder for one and a half hours, it showed a slight trace of free formaldehyd. Imitations, outside the body, of the conditions of the urine in the bladder gave practically the same effect as to the rate of decomposition of hexamethylenamin. These results show, therefore, that the conditions of the body and urine favor the decomposition of hexamethylenamin into formaldehyd when taken internally, although the process goes on very slowly. As to the excretion of free formaldehyd in the bile, pancreatic juice, milk, blood, and cerebrospinal fluid after the internal administration of hexamethylenamin no data are as yet available. The tests which were applied for the detection of the drug in these fluids apply to free formaldehyd or formaldehyd liberated by the catalytic action of sulphuric acid on hexamethylenamin.

About a year ago Professor Sollmann suggested that I investigate whether hexamethylenamin is excreted by the human saliva, either free or as formaldehyd. So far only two experiments have been made, but since these gave identical results, a preliminary communication may now be in place. A normal subject took by mouth in gelatin capsules, respectively, 0.6 and 0.3 gm., hexamethylenamin, and the saliva was collected and the following tests applied every fifteen minutes for at least one hour:

For hexamethylenamin direct, the bromin test was used, the saliva being previously boiled with a few drops of dilute acetic acid to remove the troublesome mucin and then filtered. The phloroglucin test was applied for the detection of free formaldehyd; the phenol and salicylic acid tests were also used. Checks, with the same test, were made on the same saliva before the drug was taken.

Experiment 1.—One-half hour before the drug was taken, the saliva was negative to all tests; on the addition to it of hexamethylenamin it gave positive results with all tests, while the formaldehyd test was negative. At 9 o'clock 0.3 gm. hexamethylenamin was taken. Samples tested with bromin water gave results as follows: Fifteen minutes later, cloudiness; thirty minutes later, a precipitate; forty-five minutes later, a small precipitate; sixty minutes later, a faint cloudiness. The salicylic acid and phenol tests gave corresponding results but in sixty minutes the phenol test was entirely negative. No free formaldehyd was found at any time.

Experiment 2.—One-half hour before taking the drug, saliva was negative to all tests; on adding to it hexamethylenamin it gave positive results with all tests, but the formaldehyd test was negative. At 8:50, 0.6 gm. hexamethylenamin was taken. Samples tested with bromin water fifteen minutes later gave a cloudiness; thirty minutes later, a precipitate; forty-five minutes later, a small precipitate; sixty minutes later, very cloudy; seventy-five minutes later, faintly cloudy. The salicylic and phenol tests gave corresponding results. No free formaldehyd was found at any time.

SUMMARY

The above experiments indicate that hexamethylenamin is excreted unchanged in the saliva. The greatest amount of the drug seemed to be excreted during the first thirty minutes after its administration. This is indicated by the character of our precipitates with bromin water and the color reactions obtained with the other tests. It is also in accordance with Crowe's observation on its rate of excretion in the cerebrospinal fluid, bile and pancreatic juice, and in the urine as noted by Sollmann.

I have not yet investigated whether the excretion of hexamethylenamin in the saliva has any antiseptic value. The absence of free formaldehyd makes this rather improbable. It must be remembered that the conditions in the saliva are quite different from those in the urine, bile, or cerebrospinal fluid. It is known that the liberation of formaldehyd is a very slow process. The stagnation of these fluids in the body would probably give time for this process to occur; but in the case of saliva, there is no stagnation and consequently it is rather improbable that any effective quantity of formaldehyd could ever be liberated.

LOCAL ANESTHESIA WITH QUININ AND UREA HYDROCHLORID

REPORT OF FOUR CASES*

W. O. GREEN, M.D.
LOUISVILLE, KY.

Through the courtesy of Dr. Bolling, I have had opportunity to use as a local anesthetic quinin and urea hydrochlorid in four selected cases. The preparation was supplied for experimental purposes only in 5 c.c. ampoules of a sterilized 1 per cent. aqueous solution.

Case 1.—A woman, aged 21, presented a fissure with sentinel pile in the right posterior anal quadrant. A 1 per cent. solution (50 minims) was injected and as shown by repeated tests with the needle it was necessary to distend the tissues before complete anesthesia could be obtained. It was also necessary because of a short needle to make several punctures, and it required twenty-three minutes to obtain complete anesthesia. Induration became manifest in about ten minutes and continued until the twelfth day. Some capillary bleeding, though very slight, followed the extirpation of the hemorrhoid and the incision of the fissure, which latter extended about one-half inch up the anal canal and to the depth of about one-fourth inch above and one-half inch below. There were no apparent general symptoms from the anesthetic, though the patient complained much of headache, which grew steadily worse, until the completion of the operation, and which most likely was due to fright. Before applying the dressings examination revealed a zone of hyperesthesia (to touch, not pain) extending about one-half inch from the injected area on all sides. The process of healing was uninterrupted by complications and lasted about two weeks. The anesthesia diminished until the ninth day, and normal sensation was apparently restored on the twelfth day. Throughout the healing process the surface of the wound presented a pale, grayish appearance and bled slightly on manipulation.

---

*Read before the Louisville Society of Medicine, May 5, 1910.

Case 2.—A man, married, aged 42, presented a thrombotic pile in the posterior median line about the size of a hazelnut, which was inflamed and had existed a week. The entire mass was extirpated under a 1 per cent. solution of quinin and urea hydrochlorid, 45 minims being required: Distention was necessary and anesthesia was complete in seven minutes. There was slight capillary oozing and two small vessels spurted, one of which was tied. Slight induration was noticeable about one hour after the injection, but apparently disappeared by the fifth day. Much pain was caused by the introduction of the needle and there was no hyperesthesia to touch. No general symptoms were present. Anesthesia continued in a modified degree, until the fourth day, after which there was apparently more than usual pain and tenderness throughout the remaining time of granulation. There was also, during this time, a tendency to capillary bleeding, at the times of dressing and with the movements of the bowel. The granulating area presented a pale grayish appearance.

Case 3.—The patient was a woman aged 40, married; diagnosis, external hypertrophic hemorrhoid, situated in the anterior median line. A 1 per cent. solution of the anesthetic (80 minims). was almost painlessly injected into the tissues, with two introductions of the needle. It was necessary to distend the tissues and anesthesia was complete in ten minutes. There were no general symptoms. The mass was extirpated and two small arteries spurted, and were caught with hemostats, but not tied. There was slight capillary oozing, though sharp bleeding came later from one vessel and continued for about three hours. Twenty minutes after the operation there was smarting pain which lasted four or five hours. After the pain subsided the wounded surfaces seemed incompletely anesthetized for about twenty-four hours. There was apparently no induration and hyperesthesia was not noticeable. During the process of repair the wounded surface was pale, and there was considerable pain with the movement of the bowel on manipulation of the parts, while walking or maintaining the erect posture. There was slight tendency to bleed even with the movement of the bowel. The wound healed in three weeks leaving a slight scar.

Case 4.—Female, aged 20, single. Prolapsing internal hemorrhoid, situated in the right anterior quadrant, about the size of a hazelnut. A 1 per cent. solution of quinin and urea hydrochlorid (55 minims) was injected without pain, the tissues were distended and anesthesia followed in four minutes. Induration appeared in about ten minutes and was apparent for ten days. Hyperesthesia was noticeable for about twelve days, extending over the anal canal and lower rectum. The primary incision at the base of the tumor made preparatory to applying the ligature, was followed by only slight capillary oozing. There were no general symptoms. The ligature came away on the fifth day and the entire granulating area presented a whitish appearance with little tendency to bleed. Anesthesia seemed complete for seven days and normal sensation was restored about the eighth day.

RECAPITULATION

1. Diagnosis: First case, fissure; second case, thrombotic external hemorrhoid; third case, hypertrophic external hemorrhoid; fourth case, internal hemorrhoid.
2. Solution 1 per cent. quinin and urea hydrochlorid.
3. Amount of solution used, 45 to 80 minims.
4. Distention necessary in all cases.
5. Anesthesia more or less complete; it began in a few minutes (varying from four to twenty-three), and lasted from twenty-four hours to nine days.
6. Bleeding: Capillary much reduced, arterial and venous not controlled; possibly reduced.
7. Induration in three cases appeared in ten minutes to one hour; continued from five to twelve days.
8. Normal sensation restored in twenty-four hours to twelve days, apparently.
9. General symptoms absent (in all cases).
10. As indicated the fibrinous exudate seemed absorbed in from five to twelve days.
11. Hyperesthesia for sensation present in two cases. In one hemorrhoidal case it lasted twelve days.

607 Second Street.

PELLAGRA COMPLICATING A LAPAROTOMY

RAYMOND C. TURCK, M.D.
JACKSONVILLE, FLA.

Patient.—A white woman, aged 30, born and raised in South Florida; married, and having one child aged 3. When I first saw her in December, 1908, she had had a menorrhagia for six weeks, the flow being irregularly profuse, but without pain. The patient was badly nourished, almost emaciated. Although very weak she was able to move about the room. She was markedly melancholic, or rather in varying stages of hysteromelancholia, with occasional suicidal tendencies. There was no rise of temperature or pulse and there were no definite points of pain or tenderness. She gave a history of having had dysmenorrhea for years, and of having temporarily lost her mind twice.

Examination.—I found a relaxed vaginal outlet, uterus in extreme retroflexion, marked endometritis, with both ovaries enlarged and tender. At times she talked rationally and gave me a fairly clear history of her troubles. There was no apparent loss of sense perception; the knee-jerk was slightly exaggerated; Babinski was not present; pupils reacted to both light and accommodation. The patient complained of indigestion, apparently both gastric and intestinal, and stated that she was usually constipated, but had an occasional diarrhea. Examination of the urine gave strong reaction for both indican and indol-acetic acid, but no evidence of kidney lesion. Blood examination showed secondary anemia, with many microcytes and megalocytes. The differential leucocyte count gave 66 per cent. polynuclears, 28 per cent. lymphocytes, 2 per cent. eosinophils, and 4 per cent. transitionals. At this time it appeared that the mental and constitutional symptoms were secondary to the pelvic disorders and to an intestinal autotoxemia.

Treatment and Course of Disease.—Intrauterine douches controlled the menorrhagia without difficulty. The patient was put on supportive and nourishing treatment to prepare her for operation. She was treated from Jan. 8 to Jan. 21, 1909, without much improvement, except a rise in hemoglobin to 95 per cent. Operation was performed at DeSoto Sanatorium under ether anesthesia. The uterus was curetted and a median abdominal incision made. I removed one subperitoneal uterine fibroid, did a ventrosuspension, and resected both ovaries, which were fibrous and cystic. The patient recovered nicely from the operation and the wound healed kindly. For the first few days following the operation she seemed in much better spirits and her mind was apparently clear. Following this she gradually became more and more melancholic, and after leaving the hospital lapsed gradually into a state of dementia. At this time the gastrointestinal disturbances became marked; diarrhea was more or less constant. The tongue was swollen and red, in the fifth or sixth week after operation becoming black and completely filling the mouth. During the last week there was a continued flow of offensive saliva from the mouth. When I first saw the patient she had on the backs of the hands and on the extensor surfaces of the forearms small dry scaly patches resembling a mild psoriasis. I gave this no thought at the time.

Within two weeks after operation, however, these patches increased in extent and on parts of the arms, back and chest there was a condition resembling in places a dry eczema, and in others an erythema. The patient gradually lost strength and flesh. Her insanity became violent and she died six weeks after operation in a state of acute mania.

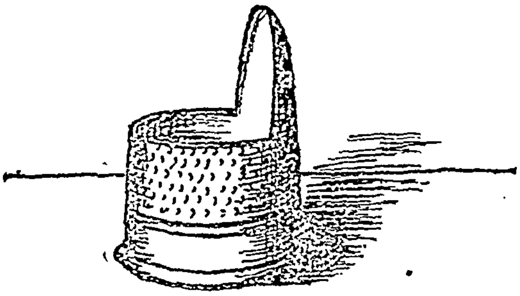
It was not until after the death of the patient and after reading Dr. J. H. Randolph's paper on pellagra[1] that it occurred to me that this case was undoubtedly pellagrous.

The interesting feature of the case, if any, lies in the apparent rapid development of pellagrous symptoms after the anesthetic and operative work.

A SIMPLE TONSILLOTOME

JOHN P. DOUGHERTY, A.M., M.D.
SIOUX CITY, IOWA

This little device may be of interest to those who remove the tonsil by means of the finger-nail, or to those who avoid the finger-nail method, solely from fear of the resultant trauma. It is in principle merely a very strong finger-nail, which can be made as sharp as desired and freely modified as to shape and length. A simple way of making it is to take an ordinary thimble of a size which loosely fits the middle finger, and which is, therefore, very loose for the index-finger on which it is to be used. A hole is filed in the top of the thimble and this enlarged until, with the exception of a lateral projection about the size and shape of a finger-nail, about half the thimble has been cut away. This projection, both at its tip and at its base, should be rather narrower than the finger-nail, and should not include any part of the top of the thimble, as this might interfere with the tactile capacity of the index-finger when thrust into and partly through the instrument. If the instrument be made but slightly sharper than the finger-nail, the tonsil can be removed neatly, quickly and without trauma, and at the same time the danger of cutting adjacent structures is largely obviated. A narrow piece of gauze or tape must be threaded through the instrument to facilitate its recovery in case it slips from the finger.



A simple tonsillotome.

In other than the tonsillar region it may also prove a useful adjuvant to finger-nail dissection, and in some cases may be used in place of a scalpel or scissors.

POPLITEAL ANEURISM SUCCESSFULLY OPERATED ON BY MATAS' METHOD

GEORGE P. HAMNER, M.D.
LYNCHBURG, VA.

Patient.—P. E., negro, male, married, aged 52, gave negative history of syphilis and tuberculosis, though he had a number of suspicious old scars on legs; probably syphilitic. He felt a dull, aching sensation in the left popliteal space a few days after stepping into a post-hole and falling backward with all the weight of his body thrown on the leg behind the knee. Aching and pain continued to grow worse until, two months after the injury, on January 7, I was called in and found the patient suffering considerably and complaining of pain in the left popliteal space, which showed a plainly visible and palpable pulsating tumor about the size of a lemon, making the diagnosis of aneurism unquestionable. The patient was put on potassium iodid grs. x t. i. d. with an increase of one grain daily while the advisability of waiting longer before operation to insure sufficient endothelial lining of the sac was under consideration. On the above treatment the pain soon disappeared and the patient seemed to improve for a time. I saw him at intervals of three or four days, and he remained very comfortable until January 31, when I was called rather hurriedly and found the patient in great pain. The tumor had suddenly increased very much in size, being now about the size of a large orange and hard and tense with pulsation not visible, and only felt slightly on deep pressure, which caused the patient to cry out with pain. The leg below the knee did not look well at all and was beginning to feel much cooler than the other, showing the effects of the pressure on the circulation. Immediate operation was advised.

Operation (February 1).—An Esmarch bandage and tourniquet were applied from the toes to the junction of the lower and middle third of the thigh, and after the tourniquet was made fast the bandage was removed and a free incision made through the skin. The sac was encountered just beneath the skin and was so thin and necrotic in character that portions of the clot protruded. The clot was turned out and the sac washed, the latter being in such a necrotic condition that the greater part of it had to be dissected out. The main trunk of the artery was located just posterior to the sac and after some little search the distal and proximal openings were found about one and one-half inches apart. It was clearly a saccular aneurism, with no collateral openings and occupied the middle third of the popliteal artery. My first intention was, of course, to do a restorative endo-aneurismorrhaphy but the sac was so friable, as to make this unsafe, so I had to resort to obliterative endo-aneurismorrhaphy, closing the openings with several tiers of sutures. I first tried to suture with fine silk but it did not stand tying well and showed a tendency to cut out. The suturing was, however, successfully done with No. 2 iodized catgut, and when the tourniquet was loosened only a small amount of venous ooze took place, which readily yielded to hot compresses. The wound was then closed, muscles, fasciæ and skin, but as the fat, which normally occupies this space, had all disappeared a small dead space was necessarily left.

Post-operative History.—The patient was taken from the table in good condition and the leg bandaged with warm cotton and hot-water bags applied. In about two hours he had reacted and the leg operated on was as warm as the other, a condition which had not existed for some days before the operation. With the exception of a temperature of 100 F. on the second day the patient appeared normal in every way until the seventh day. The dressings were taken off on the fifth day and showed a firm primary union. On the seventh day after the operation the temperature was again 100 F. The wound was again examined and showed a clean dry union. The cause of the temperature was rather puzzling until the ninth day, when pus was discovered oozing from under the edges of the bandages. This time when the dressings were removed pus was flowing freely through two small openings in the skin from deep pockets, one just behind the joint and another higher up the thigh. These pockets resulted from the dead space left when the opening was closed. They were irrigated with a

---

[1] Randolph, J. H.: Notes on Pellagra and Pellagrins, Arch. Int. Med., January, 1909, p. 553.

1 to 1,000 bichlorid solution and hydrogen dioxid and packed with iodoform gauze. In twenty-four hours the temperature had returned to normal, and in three or four days the small wounds were covered with healthy granulations. They were kept clean with the antiseptics and packed to the bottom and gave no further trouble. At the end of the third week the patient was taken to his home and in another week, four weeks from the date of the operation, he was able to get about on a crutch. He has been at work for about a week at his usual occupation, that of driving a two-horse dray.

I learned two things from this, my first experience with this operation: First, that it is much better to operate early in such cases, while the tumor is pulsating, than to wait until a clot forms with the resulting damage from pressure, as in this case; and second, that the resulting dead space should never be closed without proper drainage. I think that a small cigarette drain in the wound would have obviated the trouble I had with suppuration in the sac.

1016½ Church Street.

THE AUTOLYSIS OF PNEUMOCOCCI AND THE EFFECT OF THE INJECTION OF AUTOLYZED PNEUMOCOCCI*

E. C. ROSENOW, M.D.
CHICAGO

Pneumococci when suspended in sodium chlorid solution disintegrate and become Gram-negative. The greater the virulence the more rapid the destruction. Non-virulent pneumococci often resist disintegration unless chloroform is added. This process has been proven to be a true autolysis and not due to the action of sodium chlorid in the solution, or to the solubility of the protoplasm of the pneumococcus in water. Several years ago it was shown that the autolytic extract of highly virulent pneumococci in sodium chlorid contained an antiopsonic substance. Similar results have been obtained repeatedly since.

Further studies of the soluble substances and the autolyzed pneumococci are in progress and the following preliminary statements can be made. It seems that by means of autolysis it is possible to separate at least to a large degree the toxic from the non-toxic or antigenic parts of the pneumococcus. The part which goes into solution is the toxic portion. It causes peritonitis and leucocytosis in animals, marked local reaction, leucocytosis, and some fever when injected subcutaneously in man. The opsonic curve shows only a slight rise. It is impossible to immunize animals to any marked degree by repeated injections. Intravenous injections into rabbits may prove fatal.

The injection of the non-toxic and as it appears, the antigenic portion—the autolyzed pneumococci—on the other hand, causes practically no local reaction, only slight increase in the number of leucocytes, but a marked increase in the immunity curve as measured by the specific increase in pneumococco-opsonin.

The usual negative phase is absent. From a number of tests it appears clear that the simultaneous injection of the toxic part interferes to a marked degree with the immunity curve produced by the non-toxic portion.

The injection of autolyzed pneumococci into twenty-five patients with lobar pneumonia seems to show that we have in this material a valuable aid in the treatment of this disease. In two cases of pneumococcus empyemia it seemed to have a marked beneficial effect. Further tests will, of course, be necessary to prove this point. However, it would seem from the evidence at hand that we can by this means stimulate the formation of antibodies at an earlier period than occurs naturally by the infecting pneumococcus.

150 Michigan Avenue.

Therapeutics

ULCERS OF THE LEG

In spite of the advance in methods and technic in most surgical lines, there is as yet no one orthodox method of treating an indolent ulcer of the leg. Physicians and surgeons differ in their methods of treating this condition, and all are more or less successful. The difficulty is to select the particular treatment that is best adapted to the particular kind of ulcer in a leg with a particular condition of the circulation, at a particular age of the patient, with the particular kind of work that he must do. It is self-evident that for the successful treatment of ulcer of the leg all of the above items must be taken into careful consideration before the best treatment for the individual patient can be decided on.

There are certain principles of treatment which must be observed, but which may be carried out in different ways, while there are certain indications, which, in many instances, cannot be carried out. Under these circumstances the obstacles to success are greatly increased, and the good effect of rational therapeutic procedures is greatly impaired, and a considerable prolongation of treatment is thereby rendered necessary.

When the physician undertakes to treat a case of ulcer of the leg, he must consider whether there is a syphilitic element in the case. This is especially likely to be found when the ulcers are multiple and affect both legs somewhat symmetrically. If there is reason to believe that a syphilitic taint is present constitutional treatment, with a mercurial, such as the yellow iodid of mercury (hydrargyrum iodidi flavum), in doses of 0.015 gram (¼ grain), three times a day, after meals, may be desirable. This may be followed after several weeks by the iodid of potassium in 0.30 to 0.60 gram (5 to 10 grain) doses, well diluted with water, half an hour after each meal.

Next, it must be considered what conditions exist remote from the local lesion which tend to perpetuate it. It will at once be found that most of these ulcers are associated with impaired circulation of the limb, which in many cases has resulted in a varicose condition of the superficial veins. This impairment of the circulation may be due to valvular or degenerative muscular disease of the heart, to impairment of the function of the kidneys, to tumors in the abdomen, and, by far the most frequently of all, to pregnancy. Other less frequent causes are an hereditary weakness of the vessels, especially the veins, hard work, especially lifting heavy weights, constriction of the limbs by garters, and sitting with the legs crossed. The defective circulation in the leg often causes edema of the connective or cellular tissue, and congestion of the skin, which may become a dermatitis or an eczema, accompanied by tormenting itching.

---

* From the Memorial Institute for Infectious Diseases and the Dane Billings Fellowship in Medicine, Rush Medical College, Chicago.

Obviously the most logical and the easiest way of combating this impaired or deficient circulation in the leg is to keep the patient in bed with the affected limb elevated. But most persons who suffer with ulcer of the leg must work every day, and cannot afford the time to go to bed and wait for the ulcer to heal; hence we must try to have the ulcer heal even under unfavorable conditions.

Other resources must be utilized in order to overcome the deficient circulation. If there is constipation, with edema and congestion of the skin, a saline laxative is likely to prove of advantage by depleting the vessels of the intestines or a vegetable laxative may be of value by stimulating the secretion of the liver and intestinal glands and so promoting elimination of toxic products which impair the circulation.

If there is valvular disease of the heart or weak action of the heart not dependent on advanced muscular degeneration, the tincture of digitalis in doses of 15 or 20 drops, three times a day will prove useful. This drug, however, should not be continued in this dose if the pulsations of the heart are reduced below 60 a minute.

If the peripheral vessels show signs of weakness, and are dilated, the fluidextract of ergot, in doses of 1 to 2 c.c. (15 to 30 minims), should be given, well diluted with water, three times a day, after meals.

If there is thickening of the tissues, of if the vessels show signs of commencing arterial sclerosis, the iodid of potassium or sodium should be given in 0.30 gram (5 grain) doses, well diluted with water, half an hour after meals. After a week one dose of iodid a day is sufficient.

If the urine is scanty, or highly acid, or contains much uric acid, an alkaline diuretic should be prescribed, such as the potassium citrate in 2.0 gram (30 grain) doses, in half a glass of water, after each meal.

If the ulcer is sluggish and heals slowly the solution of potassium arsenite (Fowler's solution) given in 5 drop doses, in water, three times a day, after meals, will sometimes prove beneficial. If anemia is present, iron must be prescribed.

Turning now from the constitutional and general treatment to the local treatment, it will be instructive to read the description given by Dr. Alfred J. Buka, of Pittsburg, Pa. (*Medical Record*, Oct. 9, 1909), of the method of treatment followed in one of the divisions of the Department of Charity and Correction of the City of New York, where during five months he actually handled and treated about 125 patients who had ulcer of the leg. Buka describes this method as follows: The ulcer was first made anesthetic with a 2 per cent. solution of cocain or betaeucain. The floor of the ulcer was then curetted so that all of the granulations were removed. Sometimes where the margins were deep, the floor of the ulcer was scarified, as well as the margin. If the bleeding was free, it was allowed to go on for a few minutes. "If the ulcer bed showed a tendency to tardy or poor granulations it was livened up by painting with iodin or by destruction of the granulations with lunar caustic, 50 per cent. silver nitrate, or pure carbolic acid, to be washed off with alcohol. After the treatment for exuberant or tardy granulations the ulcer area was treated with warm 1-2000 or 1-5000 bichlorid dressings. Sterile gauze pads (about 4-6 inches) were placed in the warm bichlorid solution, and after a free removal of the excess solution, they were placed on the ulcer. Rubber tissue was placed over the gauze and the part was bandaged with 3-inch gauze (not too tight). If the patient remained in the wards rubber tissue was not used and the bandage over the ulcerous area was kept wet with bichlorid solution. All patients were instructed about the importance of rest, elevation, and aeration. After forty-eight or seventy-two hours the patients presented themselves for examination either at the clinics or in the wards. Each patient had the same kind of dressing placed upon the ulcer again and internal medication was instituted. Fluid extract of ergot was administered, 7 to 15 minims, three times a day, and this remedy was to be continued indefinitely."

After two or three dressings of this character, repeated at intervals of forty-eight or seventy-two hours "the ulcer appeared as a bright red, freely bleeding area, and on closer examination small, pinhead granulations could be seen." At this time the character of the applications was changed, as further described by Buka: To stimulate healthy granulations "iodoform (for which there is no excuse in modern esthetic medicine), thymolis iodidum (aristol), or bismuth subgallate" are used. Also frequently combined with these dusting powders were acetanilid or acetphenetidinum (phenacetin). When there is eczema around the ulcer the powder was used freely in combination with salicylic acid. He does not state the strength. A simple, efficient, and antiseptic dusting powder, however, is as follows:

℞.	Gm.	
Acidi salicyli	1	gr. xv
Acidi borici	49	or
Talci purificati	50	āā ℥iss

M. et Sig.: Use externally.

Buka says that wherever it is possible to keep the area moistened with bichlorid 1-5000, it is done. This, of course, would prevent infection, but it would seem that such solutions long continued would tend to inhibit healing rather than promote it, and the continuous application of physiologic saline solution might be better.

If the eczema which was around the sore tended to spread more widely, tincture of iodin was painted about the outer healthy surface, or on the outer zone of eczema. Such applications were repeated occasionally, or until the patient complained no longer of itching at the margins of the ulcer. A salicylic acid powder also tends to prevent the itching. When the applications cause troublesome burning, Buka found that this disappeared after the second or third application, and the patient did not again complain of it. After from three to five dressings he found that healthy granulations would be present and the irritation from eczema would cease; this from the fourth to the sixth week, at which time an "opalescent film" would be found on the ulcer surface. At this stage ointments are used, *i. e.*, after the granulations are covered with a protective layer, the above-mentioned opalescent film. Sometimes the change from irritating powders to ointments was made earlier on account of the patients' complaining of the burning. It seems inadvisable to use an ointment which will promote the growth of bacteria, especially before the granular absorbent tissue has been protected from absorption; hence the object, after the sore is made sterile, of causing granulations to occur and then become protected from absorption by antiseptic powders. This at least is the object of this treatment. A 10 to 20 per cent. ichthyol ointment was used as both stimulating and healing. When ointments are used they should be spread thickly over the ulcer. Ichthyol ointment may be made as follows:

℞.	Gm.		
Ichthyol	10	or	ʒiii
Petrolati ....ad	50		ad ʒii

M. et Sig.: Ichthyol ointment 20 per cent.

From this description certain definite principles of treatment may be deduced. First is the necessity for thoroughly cleansing the affected limb with antiseptic solutions. Those readily available and most generally useful are a hot solution of carbolic acid from 1 to 2½ per cent. (1-100 to 1-40), which is especially useful on account of its anesthetic properties, when there is considerable pain in the ulcer; solution of the corrosive chlorid of mercury, 1-1000 to 1-5000; and solution of dioxid of hydrogen in full strength or diluted with 2 to 4 parts of water. The weaker solutions of carbolic acid and corrosive chlorid of mercury may with advantage be applied continuously for a few days, especially if the patient can be kept in bed, until the congestion and inflammation of the tissues surrounding the ulcer have partially or completely subsided, and the discharge from the ulcer has considerably diminished in amount. When this stage has been reached it is necessary to use remedies which will stimulate the healing of the sore by the growth of granulations. Sometimes the stronger antiseptic solutions, as above stated, seem to inhibit the healing of the ulcer rather than stimulate it. Therefore, many times, and this is especially true when there is a profuse discharge or exudate from the ulcer, either physiologic saline solution, or often better, the official liquor antisepticus perhaps diluted, kept thoroughly applied to the ulcer by repeatedly saturating the gauze in contact with the ulcer, makes the most healing application that can be used. This solution is slightly antiseptic, while the liquor antisepticus alkalinus of the National Formulary is alkaline and not antiseptic. This solution also has healing properties.

When a powder has been applied to the ulcer, it should be covered with a pad of sterile gauze large enough to extend several inches beyond the edges of the sore in every direction. A bandage should then be applied smoothly and moderately firmly from the toes to the knee. This fulfills a third indication by applying gentle, uniform pressure which supports the circulation and tends to prevent swelling and congestion of the leg. The bandage also protects the leg from friction with the garments. and prevents contamination with dirt and infection with microorganisms. This dressing should be repeated every second or third day, according to the amount of the discharge from the ulcer.

With reference to the use of bandages to support and improve circulation, Dr. Edward Adams, of New York, (*New York Med. Jour.*, Sept. 29, 1908) writes:

> The essential feature of ambulatory treatment is a good bandage to prevent congestion, and, to my mind, Unna's bandage is the ideal one. The paste necessary for the bandage is prepared as follows: First dissolve four parts of the best gelatin in ten parts of water by means of a hot-water bath. While the fluid is hot add ten parts of glycerin and four parts of powdered white oxid of zinc; stir energetically until the mixture is cold. Always melt the paste before using by placing the receptacle in a hot-water bath, as it must be applied while hot, it solidifying on cooling and resembling rubber. The limb should be carefully cleansed with soap and water. then with alcohol, and it must be thoroughly dried before the paste can be used. After heating it is brushed on from knee to foot and a gauze bandage is applied, cutting it frequently instead of reversing, in order to prevent wrinkles; then another layer of paste and another layer of bandage, until a support of several thicknesses is obtained. If the ulcer is secreting freely, a window may be provided or the dressing changed. After the last application of the paste some non-absorbent cotton can be applied, giving the bandage a mole skin finish; or some talcum powder can be used, giving the appearance of a plaster-of-Paris dressing. The bandage can be worn anywhere from two to eight weeks.

If during the course of the healing of the ulcer the granulations grow excessively so as to become exuberant, as it was formerly the fashion to say, and project above the level of the surrounding skin, they should be touched with the nitrate of silver stick.

Another therapeutic device formerly much employed, but at present less in vogue, is the application of strips of adhesive plaster. They should be about one inch in width, and long enough to nearly, but not quite, encircle the leg. They should be applied obliquely, alternate strips overlapping each other about one-quarter or one-third of an inch, and the adjacent strips making an obtuse angle with each other. The ulcer should not only be covered, but also a space from one to two inches above and below the ulcer. A dry powder is dusted on the ulcer before the strips of plaster are applied, and the limb is bandaged over the plaster. Strips of plaster applied in this way tend to draw together the edges of the ulcer, to lessen its depth by depressing the edges, to diminish the congestion and swelling of the surrounding tissues, and by securing these results to promote healing of the ulcer.

Where an obstinate ulcer is dependent on large varicose veins, operative treatment of them may be demanded. This subject has been discussed very clearly by Dr. Edward Adams (already quoted) who writes:

> The radical method of treating varicose ulcers after healing, especially when caused by enlarged veins, is by operative interference. The operations chiefly performed are those of Trendelenburg, Schede or Mayo. Trendelenburg's operation is the ligation and extirpation of the internal saphenous vein by a longitudinal or transverse incision at the upper and middle thirds of the thigh, about one and one-half inches in length, along the course of the vein. In suitable cases the relief follows quickly, the wound healing by primary union in about ten days. The operation, however, is not without its dangers, for, in spite of complete asepsis, thrombosis of the proximal stump and embolism have occurred, giving a warning against operating without a strict indication.
>
> Schede's operation consists of a circular incision at the junction of the upper and middle third of the leg, encircling the limb, and removing all the veins to the deep fascia.
>
> Mayo's operation is by the subcutaneous method of dissection. He exposes the vein high up, divides it, and passes over the lower portion an instrument which resembles a dull wire curette. This can be wormed along beneath the skin, dissecting out the vein until it breaks, usually three to four inches from the first exposure. The instrument is reintroduced and the procedure followed as above.
>
> After an operation for varicose veins, the leg should be placed in a Volkmann splint and the patient should remain in bed for three weeks. Massage with active and passive motion should be gradual, and no active work should be attempted until three weeks more have elapsed. A supporting bandage should also be worn for at least six months after an operation of this character.
>
> The chief complication occurring with varicose ulcers is phlebitis. Rest, with elevation of the limb and a wet dressing, must be insisted on; however, if the case is seen early enough, an operation can be performed with excision of the thrombus.

When the ulcer is healed the circulation of the leg should be improved by daily cold bathing and gentle massage, and finally over a thin cotton stocking a well fitted elastic one should be worn.

SATURDAY, JUNE 11, 1910

THE SANITARY SITUATION IN CUBA

That the example of the United States during its occupancy of the Island of Cuba following the Spanish War in the matter of public health and sanitation is being followed out by the present authorities is seen in the official bulletin of the public health department, the January and February numbers of which have just been received.

The fact that Cuba has ceased to be a focus of yellow fever infection at our doors is one for which we in this country have scarcely ceased to feel and to express relief; and Americans have not been reluctant to admit that the reorganized sanitary administration of Cuba deserves credit for carrying on the work inaugurated during the American occupation. As sometimes happens, however, praise from abroad is an embarrassment at home. Local critics of the Cuban government have lately been accusing its Department of Public Health of allowing tuberculosis to increase in Cuba, while using the public funds to eradicate the disease that is most injurious to foreigners, especially Americans. To this accusation Dr. Juan Guiteras, the director of public health, replies[1] with evident feeling in the current number of the official bulletin of his department.

There was a very rapid fall in the death-rate from tuberculosis during the first years of American intervention; but Dr. Guiteras says that this was due to the fact that the enormous mortality of the reconcentration régime had used up the material that furnished the tuberculosis mortality. This decrease was followed by an increase when the children who had survived the miseries of reconcentration arrived at tuberculous age. The influence of the sanitary measures instituted at the time of the intervention and developed and carried out since is shown very clearly in recent years after reestablishment of the natural levels. The Cuban health department has been developing its plans for the last ten years, and the tuberculosis death-rate has fallen from 21.42 per ten thousand in 1900 to 14.9 in 1908. The fall in the mortality from tuberculosis in Cuba, Dr. Guiteras says, has been no slower than in France, Ireland, Norway and portions of Austria-Hungary. The statistics for 1909 are not yet available, but it is believed that the mortality from tuberculosis as well as the general mortality has continued in its descent since the adoption of preventive measures during the first American intervention and since the nationalization of the sanitary service and the creation of a secretary of public health with a place in the cabinet. The director of the health department admits that the immediate results in the campaign against tuberculosis contrast strongly with the results in the campaign against smallpox and yellow fever, but he insists that this is not due to incompetency or neglect. The campaign against yellow fever, he says, is not carried on out of regard for treaties but out of regard for humanity, for the good name of the Cuban people and for the upbuilding of a strong and capable race.

Dr. Guiteras' defense of his department seems a good one; and his resentment at undeserved censure is natural. From this distance, however, we may be permitted to observe that Cuba, having a department of public health to criticize, is to that extent more fortunate than the United States. Moreover, if writers in the Cuban political press, whatever their motives or purposes, find public health measures a good theme on which to harp, this would seem to show that the public mind is either interested in or open to the subjects of hygiene and public well-being—in short, that a healthy public opinion on these subjects is in process of formation. Still more, it is in itself a testimony to the enormous advance which Cuba has made that it is now possible to pick out for criticism a really or supposedly weak spot in the condition of public health in Cuba. Remembering the Havana of old, once called "the filthiest city in the world," if we can suppose that the words "public health" had any other than a sarcastic meaning in the Cuba of Spanish days, can we imagine a Cuban public with any interest to spare for such an abstraction?

"When we contemplate the true sanitary regeneration of the old Spanish colony," says Dr. Guiteras; "when we study the increment in the Cuban population owing both to the increase of natality and the decrease of the mortality; when we can point to the disappearance of smallpox, the reduction of the mortality from malaria to the extent of bringing it down from the first to the eighth place in our records of mortality; when we can place to our credit the eradication of yellow fever with its average yearly record of 600 deaths of Spaniards in the city of Havana alone, the disappearance of the borras fever, so fatal to Cuban children; the gradual decrease of the mortality from infantile tetanus and tuberculosis; when we have seen this tropical country come into competition with the lands most favored by what used to be called a salubrious climate; when we contemplate all this work in the pride of Cuban nationality, we must feel deeply pained to hear it stated that the public treasury is employed by the Department of Public Health mainly to 'prevent the disease that may affect the stranger and more especially of American nationality.'"

---

[1] Guiteras, J.: Tuberculosis in Cuba, Sanidad y Beneficencia, January-February, 1910, p. 6.

We believe that our Cuban confrères can afford to disregard the light affliction of an unjust criticism, which is but for a moment, seeing that the achievements of the past and the faithful cultivation of the opportunities of the future are sure to work for them a far more enduring weight of glory.

FOURTH OF JULY AND TETANUS ARE COMING

We await the returns from the coming Fourth-of-July casualty list with interest, but with only a moderate amount of optimism. After seven years' experience in the compilation of the statistics of this day of wanton bloodshed and slaughter, we have passed through the stage of righteous indignation and are resigned to doing our best, in the hope that some day the indignation that we have felt will become transmuted into public opinion that will lead to the long-urged reforms. There are not wanting signs that the awakening is coming. The public press, which has always taken an active part in the campaign, seems to recount more instances than in previous years of communities where something is being actually accomplished in the way of prevention. In many cities and towns citizens' committees or other organizations have secured reforms or prohibition of the sale of dangerous explosives, while in many places there has been substituted a program of public exercises and illumination far more fitting to the occasion of the anniversary of American independence than is the annual carnival of noise, smoke and bloodshed by which we have desecrated the day for so many years. Enough cities have tried with success the experiment of enforcing laws prohibiting the use of explosives on Independence Day to establish its feasibility, and it is within the power of every community to rid itself of this annual catastrophe; all that is needed is an efficient and clear-seeing chief magistrate, or a few active public-spirited citizens, or some energetic organization which sees its opportunity for service in this matter. Here is a place where medical societies have done good work in a few localities, and there is an unexcelled chance for efficient service by every society located in a town where dangerous methods of celebration are permitted; but some more active and persistent exertion than the passing of resolutions is required if results are to be obtained.

The wide-spread use which has been made of the statistical material collected by THE JOURNAL after each Fourth-of-July celebration is highly gratifying, and we shall continue the accumulation of statistics this year as before.

Last year we were disappointed by an unexpected and not inconsiderable increase in the number of tetanus cases, which fact incites us to continue the urging of vigorous prophylactic measures by physicians who attend to wounds received from explosives. Nothing less than thorough surgical cleansing, supplemented by a preventive dose of at least 1,500 units of tetanus antitoxin, should suffice to satisfy the conscience of any physician. Certainly the experience of the last six years has been conclusive enough as to the almost absolute protection afforded by tetanus antitoxin when given early to patients with properly treated wounds of this kind. It is a matter of some interest that nearly all the recorded cases of failure of tetanus antitoxin to prevent tetanus have occurred in Europe; the reason for these failures is almost certainly to be ascribed to the inferior quality of antitoxin which is on the market over there. Anderson[1] states that the tetanus antitoxin in use in this country, as tested by the Public Health and Marine-Hospital Service, showed much higher antitoxic value than most of the European specimens; the American antitoxins on the market before the adoption of a standard unit containing in different samples 434, 166, 77, 700, and 769 units per c.c., as contrasted with 40, 40, 83, 66, and 50 units in the French and Italian serums. In cases in which the wound does not heal well because of mixed infection, it is desirable to repeat the antitoxin, for, as Rowan[2] has pointed out, in these cases, the tetanus bacilli may continue to multiply in the pus-infected tissues until the injected antitoxin has been exhausted or eliminated, when there may occur a late development of tetanus.

There is nothing new to advocate in the matter of curative treatment, unfortunately. As ever, in the cases with a short incubation period the patients die with but few exceptions, while in those with longer periods of incubation the patients sometimes recover under the most diverse treatments. Free use of antitoxin is indicated, since it will at least neutralize such toxin as is free in the circulation and thus lessen the amount that will act on the nervous tissue; and there seem to be both theoretical and clinical grounds which support the practice of administering it by the intraspinal route when practicable. The use of magnesium sulphate, eucain, or other sedatives by the spinal route is still in the experimental stage, with sufficient favorable results on record to warrant trial by those who are competent to make and to observe such experiments.

ACCELERATIVE AND RETARDATIVE FUNCTIONS OF THE GLANDS OF INTERNAL SECRETION

Important and interesting facts have been brought to the attention of the medical world as a result of investigation into the functions of the ductless glands. It is to the correlation of these facts that we must look for a satisfactory understanding of the part played by these glands in the regulation and maintenance of life. The difficulties of research have been so many and the establishment of facts so gradual that progress in our knowledge of these glands has seemed slow. At present, however, there has accumulated a sufficient number of observations to render it probable that some insight into the workings of these obscure glands might result from an attempt to unify the isolated facts.

---

[1] Anderson, John F.: The Commercial Preparations of *Tetanus* Antitoxin, THE JOURNAL A. M. A., Jan. 22, 1910, liv, 253.

[2] Rowan, Charles J., The Prophylactic Use of Tetanus Antitoxin, THE JOURNAL A. M. A., Feb. 12, 1910, liv, 533.

This work of unification has been very well begun by members of the Vienna school. They have pointed out the striking fact that, beside their own specific action, the ductless glands interact among themselves, and that any disturbance in the working of one results in an upset to the equilibrium of the rest; in consequence, the body metabolism is disturbed in many of its subdivisions—protein, carbohydrate, fat, and mineral. It has been the special service of this school to attempt an arrangement of the ductless glands into groups using disturbances of the metabolic functions of the body, to which they give rise, as a basis for classification.

On broad lines of function the ductless glands may be divided into two groups: (1) the accelerative, and (2) the retardative.

Into the first group fall the thyroid, the adrenals and the hypophysis. On study of the reactions of the body to injections of their prepared substances and on observation of experimental interference with their functions it has been found that all three increase protein exchange, the most marked effects being noticeable in the case of the hypophysis. The adrenals cause mobilization of the carbohydrates, and the thyroid leads to increased destruction of fat.

Into the second group fall the pancreas and the parathyroids. Both retard protein destruction, the pancreas being the more effective. Both likewise restrain the mobilization of carbohydrate; here too the pancreas is the more active. Likewise, the pancreas causes decrease in fat consumption.

A consideration of the relation of the ductless glands to mineral metabolism is of much interest. Feeding of thyroid tablets has been found to be followed by increased output of phosphates by the intestines, while feeding of hypophysis leads to a decrease in phosphates in the urine and an increase of the same in the feces. After the administration either of thyroid or of hypophysis extract, dogs show a great increase of calcium in the feces and of magnesium in the urine. With epinephrin it is different; the ratio of nitrogen to phosphorus pentoxid decreases and the calcium and sodium output is increased. The parathyroids exert a special restraining influence on calcium metabolism as shown by the increase in calcium in the urine and loss in the tissues when this gland is removed experimentally. Such findings suggest the inquiry whether the ductless glands directly influence the metabolism of the minerals of the body, or whether such changes are secondary results of some primary general disturbance. [illegible] in the [illegible]titative experiments alone can solve this

Guiteras says,[1]

land, Norway an the thyroid and of the parathyroids on statistics for 1909 are strikingly different from one

on of the parathyroids the galvanic irritability of the nerves decreases, while in dogs deprived of the thyroid it increases. This may possibly be brought into relation with the loss of calcium in parathyroidectomy, as calcium strongly decreases the irritability of the central nervous system.

Do the ductless glands have any influence on the blood? On this point some experimental findings are of interest. After epinephrin injection a leucocytosis develops, which is of the neutrophilic polymorphonuclear type; there is also a decrease in eosinophils. Thyroid extract likewise causes a decrease in eosinophils, which is slower to make its appearance, while hypophysis extract has no definite influence.

A comparison of the action of the glands in the same group has been fruitful. For example, both epinephrin and hypophysis extract, when injected into dogs, raise the blood-pressure, but the action of the hypophysis is slower and weaker. Hypophysis extract slows the heart but little while epinephrin does so powerfully. On section of the vagus nerve no change in rate takes place after hypophysis injection, while in the case of epinephrin a marked increase in rate comes on. Pituitary extract narrows the coronary arteries while epinephrin widens them; the opposite is true of the kidney vessels, a fact which probably explains the polyuria in some diseases of the hypophysis.

Do the ductless glands act through the discharge into the circulation of specific hormones? Such is the conception of Falta regarding the action of epinephrin, which he considers as having a special affinity for the sympathetic nerves. The mobilization of sugar in the liver is, according to his view, under the influence of the sympathetic, by mediation of the adrenals.

Though the observations on the activity of this group of glands are still meager, and their interpretation difficult, the work of unifying these results has already forecast important relations between them. The activity of many laboratories in this special field promises much for the future. Perhaps it is not too much to hope that, through the study of these glands, important light may be shed on the etiology and treatment of the still obscure metabolic diseases.

THE CARNEGIE FOUNDATION REPORT ON MEDICAL EDUCATION

So many marvelous things have been brought about in the domain of medical education during the past few years that great changes now seem commonplace and events of even greater magnitude would be taken as a matter of course. Nevertheless, all who are acquainted with the work which the Carnegie Foundation for the Advancement of Teaching has been doing in the investigation and standardizing of universities and colleges, have been awaiting with eager interest that body's report on medical education. The report has just appeared and undoubtedly will meet the highest expectations of those who have been watching for it.

---

[1] Guiteras, J.: Tuber
January-February, 1910, p.

As has been stated in these columns,[1] the Carnegie Foundation was established in 1905 by Andrew Carnegie, who set aside a fund of $10,000,000 to provide retiring allowances and pensions for teachers in colleges and universities. At first, state universities were excluded, but later the endowment was increased by $5,000,000 in order that the benefits of the fund might be extended to them also. Realizing that not all institutions which call themselves colleges or universities are worthy of such titles, the foundation made an investigation of educational institutions in order to determine which were acceptable. Only the professors of such colleges as came up to the standards fixed by the foundation were eligible to receive pensions. Many of the universities found acceptable had medical departments and already not a few medical teachers have retired on Carnegie allowances. The Carnegie Foundation consequently stands for the advancement of medical teaching to quite the same degree as it stands for the advancement of teaching in other branches.

At the beginning, the investigations of the foundation were directed toward the college as the portion of the educational system most directly benefited by the endowment. This led to a study also of the university with its various departments, including the medical school. In the natural evolution of the foundation's work, therefore, medical education was taken up, and apparently at the psychologic moment, following as it did the first inspection made by the Council on Medical Education and being made simultaneously with the Council's second inspection. The reports of both of these bodies will have added importance, inasmuch as the two deal largely with the same problems.

The investigation of all the medical schools of the United States and Canada has been completed, and apparently with the same thoroughness as the study of other institutions in which the foundation has been interested. The foundation has quite properly taken the position that medical schools as well as colleges and universities are in truth public-service corporations, whether supported by taxation or private endowment; that the public has a right to know the facts concerning their equipment and ability to furnish education; and that only by a publication of the facts, unbiased by local ambitions or points of view, can the best interests of education be subserved. From the view-point of the needs and qualifications of the medical student and the interests of the general public, the foundation has examined carefully into the demand for physicians, the number of colleges necessary to satisfy that demand and the standards of preliminary education, teachers, laboratory equipment and clinical facilities which could reasonably be required of the medical schools.

Emphasis is laid on the fact that the social order is best served when the number of men entering a given profession reaches and does not exceed a limited ratio and that the present condition of the medical profession, overcrowded by ill-trained physicians, is very unsatisfactory. The illustration is used that "when six or eight ill-trained physicians undertake to make a living in a town which can support only two, the whole plane of professional conduct is lowered, and, in the struggle which ensues, each man becomes intent on his own practice, public health and sanitation are neglected, and the standards of the profession tend to demoralization." The best interests of the general public are certainly not best subserved under such conditions.

The report also suggests that with the present oversupply of medical schools, a state having no medical schools may be supplied with as good, or possibly better, physicians than other states which may possess several medical colleges, and that, at the present time at least, a community's best interests may be best served by the absence of medical colleges.

Regarding sectarian medicine, the foundation has taken the only logical position, namely, that, regardless of the method of treatment employed, all practitioners alike should have a thorough grounding in the fundamental medical sciences. Unless the physician is sufficiently well trained to make a proper diagnosis, treatment by any method would be mere guess-work, unscientific, and more apt to do harm than good.

This report is evidently the result of an enormous amount of painstaking work and is worthy the most careful study.[2] Coming from an agency outside and independent of the medical profession, it is sure to have a most profound influence on medical education in general, and claims of partiality or prejudice cannot be made against it. It is the more valuable since it comes from an agency whose function it is to investigate, compare and standardize all departments of education, technical and professional as well as general and collegiate, and indicates how the medical school, as a part of the educational system of our country, compares with the other parts of that system. If the conditions revealed by this extensive investigation are given a wide publicity, the result to medical education can be only good. The actual facts, in the end, will be more helpful than the poetry of the medical school catalogues and advertisements, especially to state licensing boards, some of which are now endeavoring to ascertain the actual character of the medical schools that send them applicants for license. Noteworthy forward steps, especially in the line of consolidation of medical schools, have already received effective encouragement from the Carnegie Foundation, and undoubtedly, this report will call the attention of men of wealth to the need of endowments for medical education. It is evident that the Carnegie Foundation is in a position in which it may exert a powerful and growing influence for good on the development of medical education in this country.

---

WOMAN'S MEDICAL COLLEGE OF BALTIMORE PERMANENTLY CLOSED

A letter from Dr. John R. Abercrombie, dean of the Woman's Medical College of Baltimore, informs us that, at a recent meeting of the faculty, it was decided to close that college permanently at the end of the present session. The reasons given are that sufficient funds were not available to make the improvements in the equipment and teaching facilities which the faculty considered essential and that the faculty preferred to close the college, rather than continue it as a medical college of other than the first rank, thereby preserving the excellent record maintained during the twenty-eight years of its existence. This is another instance in which faculty members have been willing to sacrifice personal interests that medical education might be improved, better standards prevail, and the public be provided with better trained physicians. After all, it is not strange that we seldom hear of such action as this being taken by colleges conducted solely for profit. It is almost invariably the colleges with higher ideals than those based on commercialism which, seeing the impossibility of maintaining those high ideals, voluntarily close. The colleges inspired by profit will enforce reasonable standards or close only when required to do so by state licensing boards.

THE ST. LOUIS SESSION

As we go to press the St. Louis session promises to be one of the most successful in the history of the Association. The weather is magnificent and augurs well, not only for a highly satisfactory Session, but also for the success of the outdoor entertainments planned. The first meeting of the House of Delegates was held Monday under the presidency of Col. Gorgas, and the usual routine business was transacted; the account of the proceedings appears on page 1963. A cordial reception was given to the visiting physicians. The registration on Monday was 1,400 and that number was greatly exceeded on Tuesday.

Medical News

ARKANSAS

Sanatorium for Odd Fellows.—The Arkansas Grand Lodge of Odd Fellows has selected a farm near Walnut Ridge, Lawrence county, as a site for a tuberculosis sanatorium for which $100,000 was devised under the will of the late A. W. Shiery, Little Rock.

Personal.—Dr. Morgan Smith, Little Rock, has been appointed assistant secretary for Arkansas, of the Rockefeller Sanitary Commission.——Dr. William W. Rice has been appointed president and Dr. Albert S. Buchanan, secretary of the Prescott Board of Health.

Commencement.—The fourth annual graduating exercises of the College of Physicans and Surgeons were held in Little Rock, April 29. Dr. C. H. Hoffman delivered the address to the graduating class which numbered 26 and the diplomas were presented by Dr. Joseph P. Runyan, president of the board of directors of the college.

County Society Meetings.—At the annual meeting of the Randolph County Medical Society, held in Pocahontas, April 21, Dr. John W. Brown, Swartz, was elected president; Dr. William E. Hughes, Pocahontas, secretary; Dr. Carl Scheidt, Pocahontas, treasurer; Dr. H. B. Hull, Ravenden Springs, delegate to the state society, and Dr. Thomas Z. Johnson, Holmes, alternate.——Howard County Medical Society at its recent meeting in Ashdown, elected Dr. W. M. Gibson, Nashville, president, and Dr. William H. Toland, Mineral Springs, delegate to the state society.

CONNECTICUT

Tuberculosis Farm Sanatorium Prospers.—At the sixth annual meeting of the New Haven County Antituberculosis Association, held at the Gaylord Farm Sanatorium, Cook's Hill, Wallingford, Dr. Edward T. Bradstreet, Meriden, was elected a director. The average number of patients under treatment during the year was 59, and the total number of patients treated 117. Up to date 1,007 have applied for admission to the sanatorium, of whom 668 were accepted. During the last year 62 patients remained at the sanatorium for less than three months, 50 of whom left the institution distinctly improved; 104 patients remained for three months, and of these 23 were incipient cases, of which 21 were discharged with the disease arrested; 75 patients came with the disease moderately advanced, and of these 51 were discharged with the disease arrested, and 11 improved; 6 patients came in a very advanced condition of the disease; in 2 of these the disease was arrested and in 2 the patients improved.

Societies Meet.—At the annual meeting of the Norwich County Medical Society, in Norwich, May 16, the following officers were elected: Dr. Patrick H. Harriman, president; Dr. Dennis J. Shahan, vice-president, and Dr. William B. Casey, secretary and treasurer, all of Norwich.——At the one hundred and eighteenth annual meeting of the Tolland County Society, held in Rockville, April 20, the following officers were elected: President, Dr. Cyrus E. Pendleton, Hebron; vice-president, Dr. Frank M. Dickinson, Rockville; secretary and treasurer, Dr. Elip P. Flint, Rockville; councilor, Dr. Thomas F. Rockwell, Rockville, and delegate to the state association and censor, Dr. Frank L. Smith, Stafford Springs.——At the meeting of the newly organized Connecticut Society of Social Hygiene, held in Hartford, May 14, Dr. Phineas H. Ingalls was elected president; Dr. Carles S. Stern, treasurer; Dr. Thomas N. Hepburn, secretary; Dr. Oliver C. Smith, chairman of the treatment committee; Dr. Frederick T. Simpson, chairman of the publication committee, and Dr. Alva E. Abrams, chairman of the educational committee, all of Hartford.

DISTRICT OF COLUMBIA

District Association Election.—At the annual meeting of the Medical Association of the District of Columbia, April 26, Dr. Noble P. Barnes was elected president; Dr. Edwin B. Behrend, vice-president; Dr. Luther H. Reichelderfer, secretary, and Dr. Frank Leech, treasurer.

Personal.—Dr. Thomas E. Satterthwaite, New York City, was a guest of honor at the annual dinner of the Washington Medical and Surgical Society, May 4, and delivered an address on "Some Newer Conceptions of Myocardial Disease."——Dr. Henry W. Miller, clinical director of the Government Hospital, Washington, has been appointed superintendent of the Maine Insane Hospital, Bangor.——Dr. Francis Dowling, Cincinnati, gave an illustrated lecture, May 27, before the U. S. Naval School, Washington, on "The Medical Giants of France." The occasion was the eighth anniversary of the founding of the school.

Pasteurized Milk Laboratory Opened.—Exercises attendant on the formal opening of the Nathan Straus Pasteurized Milk Laboratory were held at George Washington University Medical School, May 11. Hon. Jacob H. Gallinger, M.D., U. S. senator from N. H., presided and addresses were made by Surgeon-General Walter Wyman, Dr. A. D. Melvin, chief of the Bureau of Animal Industry, Hon John Johnson, commissioner of the district; Dr. William C. Woodward, health officer of the district; Dr. Milton J. Rosenau, professor of preventive medicine and hygiene in Harvard University, Dr. James H. M. Knox, Jr., Baltimore, president of the National Society for the Prevention of Infant Mortality, and Dr. Arthur R. Green, medical director of the Nathan Straus work in New York City.

INDIANA

Antituberculosis Society Organized.—The Deleware County Antituberculosis Association was organized at Muncie, May 5. Dr. William J. Molloy was elected vice-president and Drs. Hugh A. Cowing, Clarence G. Rea, Clay A. Ball and Earle S. Green were elected members of the executive committee.

Found Guilty.—Dr. Eugene V. Redlinger, Huntington, charged with incest and the crime of abortion on his stepdaughter, is said to have pleaded guilty to the charge of abortion, April 29, and to have been sentenced to be imprisoned in the penitentiary for a term of from three to fourteen years and to pay a fine of $500.

District Society Meetings.—At the annual meeting of the Twelfth District Medical Society, held in Fort Wayne May 17, the following officers were elected: President, Dr. Fred A. Metts, Ossian; vice-presidents, Dr. Douglas A. Swartz, South Whitley, and Dr. Woodward H. Hayes, Albion, and secretary and treasurer, Dr. Garrett Van Sweringen, Fort Wayne. In the evening Dr. Mazyck P. Ravenel of the University of Wisconsin delivered an address on "The Transmission of Bovine Tuberculosis to Man."——The Ninth Councilor District Medical Society held its annual meeting in Tipton, May 20, and elected the following officers: President, Dr. Andrew S. Dickey, Tipton; vice-presidents, Dr. Edgar Cox, Kokomo, and Dr. William J. Fernald, Frankfort; secretary-treasurer, Dr. Paul J. Barcus, Crawfordsville, and assistant secretary-treasurer, Dr. George T. Williams, Crawfordsville. The next meeting of the society will be held in Kokomo.——The sixth annual meeting of the Indiana Fourth District Medical Society was held in Lawrenceburg, May 27. Dr. John P. Ward, Vevay, was elected president; Dr. John Elfers, Rising Sun, vice-president; Dr. Curtis Bland, Greensburg, and Dr. James H. Green, North Vernon, treasurer. The next meeting will be held in Greensburg.

MARYLAND

Personal.—Dr. J. Frank Miller, a graduate of the Baltimore Medical College, 1909, has opened an office in Reisterstown, Baltimore county.

Aged Physician Convicted.—Dr. David W. Jones, Hagerstown, is said to have been found guilty, May 25, of attempted malpractice on a young woman and to have been sentenced to pay a fine of $100 and costs.

Tuberculosis Sanatorium Managers Meet.—The managers of the Maryland State Tuberculosis Sanatorium at their annual meeting, May 19, reelected Dr. H. Warren Buckler, Baltimore, vice-president; Dr. Victor F. Cullen, state sanatorium superintendent, and Drs. Edson M. Glidden and W. Miles Garrison, assistants.

Health Officers Appointed.—The following have been appointed health officers of Carroll county: Taneytown, Dr. Franklin H. Seiss; Uniontown, Dr. Luther Kemp; Myers, Dr. Levi Wetzel; Woolery's, Dr. Robert F. Wells; Freedom, Dr. Milton D. Norris; Manchester, Dr. John F. B. Weaver; Westminster, Dr. Charles R. Foutz, for the district and at large; Hampstead, Dr. Richard C. Wells; Franklin, Dr. Edwin D. Cronk; Middleburg, Dr. Charles H. Diller; New Windsor, Dr. George H. Brown; Union Bridge, Dr. James Watt; Mount Airy, Dr. William E. Gaver; Berrett, Dr. Daniel B. Sprecher.

MASSACHUSETTS

Bequest to Hospital.—By the will of the late Mrs. Annie Prescott Lincoln, Boston, $25,000 is devised to Grace Hospital, formerly Emergency Hospital, Boston, for a bed to be maintained in memory of her husband, Joseph Bates Lincoln.

District Medical Society Elects Officers.—Berkshire District Medical Society, at its annual meeting held in Pittsfield, May 3, elected the following officers: President, Dr. Harry B. Holmes, Adams; vice-president, Dr. Clifford S. Chapin, Great Barrington; secretary, Dr. Isaac F. Dodd, Pittsfield; treasurer, Dr. Joseph D. Howe, Pittsfield; trial commissioner, Dr. John J. Hassett, Lee; councilors, Drs. James F. A. Adams, Pittsfield; Lyman A. Jones, North Adams, and Orland J. Brown, North Adams, and censors, Drs. James F. A. Adams, Pittsfield; Albert T. Wakefield, Sheffield; Martin M. Brown, North Adams, Stephen C. Burton, Pittsfield, and John B. Thomas, Pittsfield.

NEW YORK

Public Health Association.—The Rochester Public Health Association held its annual meeting, May 10, and adopted resolutions commendatory of the stand taken by the local officials for the preservation of the cleanliness of the city and for proper sanitation. Dr. Montgomery E. Leary was elected secretary and supervising director of the association.

Attempt to Defeat Undesirable Bill.—A bill has been presented to Governor Hughes and to Mayor Gaynor which changes the existing medical law in regard to the fines imposed on violators of the medical law. At present when violators are successfully prosecuted the fines go to the Medical Society of the County of New York for the support of its work in seeking out offenders. The new bill adds, "Provided, however, that in the City of New York no fines shall be paid to any such societies, but shall belong to the said City of New York." At the present time practically the only check on unlicensed practitioners, midwives, druggists selling abortion drugs, quacks, corporations advertising the practice of medicine by unknown physicians, and fakers of all kinds who practice medicine under the cloak of religion or occultism, is the active prosecution of the Medical Society of the County of New York and hence it is urged on all the members of the county society that they use their influence to prevent the passage of this bill.

New York City

Smallpox in Manhattan.—Five cases of smallpox were recently detected in a tenement in Harlem. It was found that many persons had been exposed and the Board of Health made over 500 vaccinations in the immediate neighborhood.

Crusade Against Wood Alcohol.—The first cases in the present campaign against wood alcohol that is being conducted by the Board of Health have been found guilty and fined $100 and $150 for selling adulterated whisky. Of the samples collected on the East Side and analyzed, 20 per cent. were found to contain wood alcohol. Several cases have been put over as it is expected that the United States government will take some action against the wholesalers who have sold the poison to the retailers.

Inebriate Bill Signed.—Mayor Gaynor has approved the bill passed by the legislature which permits the board of estimate to establish a commission for dealing with inebriates and a hospital and industrial colony to be used for the reformation of drunkards. It has been stated that the board of estimate will not furnish money for the scheme as drunkenness is decreasing very markedly in recent years and it is claimed that present educational and social work is largely doing away with the evil.

A New Move to Guard Public Health.—Dr. Charles Mallory Williams, Executive Librarian of the New York *Academy of* Medicine has asked for a collection of the reports of committees appointed at various times to investigate questions of public health so that they may be available for workers. Dr. Williams would like to have the reports of investigations along such lines as harbor pollution, the alcohol question, the prevention of tuberculosis and of occupational diseases and the sanitation of tenements.

To Establish Optometry Course.—Columbia University has just sent out announcements that it will start the first optomety course to be offered by any college or university in this country. The course will begin in September and intends to equip graduates so that they may examine people's eyes and fit glasses, but they are not to use drugs. The course will be made a part of the department of physics. The Michigan State Optical Society has telegraphed that it will give the first free scholarship in the new course.

Free Dentistry for School Children.—The free dental clinic that was established in January on One Hundred and Twenty-first street to care for the teeth of school children has completed its first four months of work. During this period more than 5,000 school children have been treated. The Department of Health maintains the clinic and children are not treated until a personal visit has been made to the home of the child to see that the parents are unable to pay for treatment. Dr. S. Josephine Baker, chief of the division of child hygiene, states that out of 323,000 school children examined during the 1908-09 school year 183,000 had defective teeth.

New Hospital Building for Post-Graduate Medical School.—Work has been commenced on the new building for the New York Post-Graduate Medical School, which is to cost $6,000,000, making the institution's capacity about 400 beds. The building proposed is to be twelve stories in height and will include a tower with rooms for fifty private patients and a pavilion on the roof for open-air treatment. A loggia on three floors open to the street front and to the rear is also planned, where beds can be kept permanently with exposure to the air. In addition, three long balconies to the eastward are proposed, and the entire top of the main building, seven stories high, with the exception of the space taken up by the tower, will be occupied by a roof garden, so that unusual provision will be made for giving the patients fresh air. There are to be eight small operating rooms and a number of well-equipped laboratories for research work. After the new building is completed the present quarters of the Post-Graduate, adjoining, will be converted into a nurses' home in connection with the college.

Buffalo

Commencement Exercises.—The annual commencement exercises of the Medical Department of the University of Buffalo were held May 27 when a class of thirty-eight received diplomas. Dr. Matthew D. Mann delivered the Doctorate address.

Dinner to Dr. Mann.—A dinner was given to Dr. Matthew D. Mann by the Alumni Association of the University of Buffalo, May 26, on the occasion of Dr. Mann's retirement as Dean and Professor of the department of Obstetrics and Gynecology. A loving cup was presented to Dr. Mann by the faculty of the University with suitably embossed resolutions by the graduating class on it.

Personal.—Drs. Roswell Park, Charles Cary and Gustav Hitzel, Buffalo, have started for Europe.——Dr. Roswell Park, Buffalo, has resigned as a trustee of the J. N. Adam Memorial Hospital.——Lieut. Col. Albert H. Briggs, major of the 65th Infantry, N. G. N. Y., has been promoted to Chief Medical Officer of the 4th Brigade and Dr. Nelson G. Russell has been appointed Surgeon of the regiment with the rank of Major. Dr. Carroll J. Roberts has been promoted to Captain and Assistant Surgeon and Dr. William T. Getman has been appointed Assistant Surgeon with the rank of 1st Lieutenant.

PENNSYLVANIA

Negroes League Against Tuberculosis.—Fifty of the leading negroes of western Pennsylvania on May 21 applied for a charter for the Negro Tuberculosis Hospital League, to provide separate tuberculosis sanatoria in the state for the afflicted of their race. The tuberculosis hospitals of the state refuse to admit them, although such hospitals which have state aid, are willing to and do furnish milk, eggs and other foodstuffs needed by negro consumptives in their homes. It is the intention to raise a fund to get state aid to erect one hospital near Philadelphia and another near Pittsburg.

Philadelphia

Personal.—Surgeon-General George H. Torney, U. S. A., and Surgeon-General Charles F. Stokes, U. S. N., will be the guests of honor at a reception given by the Medical Club of Philadelphia, at the Bellevue-Stratford Hotel, Friday evening, June 17.——Dr. J. H. Parson, of London, England, the official guest of the Section on Ophthalmology of the American Medical Association, was the guest of honor at a dinner given by Dr. George E. de Schweinitz at the Bellevue-Stratford Hotel, May 31.——Dr. Alfred Saenger, Hamburg, Germany, was the guest of honor at a dinner given by Drs. Francis X. Dercum and Charles K. Mills at the Art Club on May 31.——The honorary degree of LL.D. was conferred on Dr. S. Weir Mitchell by Jefferson Medical College at the annual commencement exercises, June 6.

Hospitals in Philadelphia Improved.—More than fifty hospitals at present supply the physical and teaching requirements of this medical center, and these plants are undergoing constant expansion. The Rush Hospital for the Treatment of Consumption and Allied Diseases, at Lancaster avenue and Thirty-third street, on May 21, opened for inspection of the public the newly completed portion of its intended group of buildings. The University Hospital on May 12 broke ground for a new group of laboratory structures at Pine and Thirty-seventh streets. A new section of the Nurse Training School dormitories (with capacity for 40 additional nurses) at the Philadelphia General Hospital, Pine and Thirty-fourth streets, was opened May 12.

VIRGINIA

Northern Neck Physicians Hold Meeting.—At the annual meeting of the Northern Neck Medical Association, the following officers were elected: President, Dr. Andrew C. Fisher, Emmerton; vice-presidents, Drs. C. T. Pierce and Loren E. Cockrell, Reedville; secretary, Dr. Robert O. Lyell, Warsaw, and treasurer, Dr. Walter N. Chinn, Hague.

Personal.—Dr. Roscoe C. Carnal, Ballsville, has been appointed hookworm inspector for the district composed of the counties of Princess Anne, Norfolk, Nansemond and Isle of Wight.——The Norfolk school board has elected Drs. Julian A. Norfleet, S. Roszel Donohoe, Millard P. Doyle and J. Judd Miller medical examiners for the public schools of the city.

WASHINGTON

State Medical Board Appeals.—The State Medical Board, on May 13 gave notice of appeal to the Supreme Court from the decision of the Superior court of King's county ordering the Board to grant a physician's license to Mrs. Lucile Berfield Hazzard, a woman who is said to have used starvation methods in treatment of disease.

Hospital Corner Stone Laid.—The corner stone of the new Providence Hospital, Seattle, was laid with impressive ceremonies by the Bishop of Seattle, May 1.——The contract for the addition of a new wing to St. John's Hospital, Ketchekan, has been awarded. The wing will be two stories in height and will contain operating rooms, wards, private rooms, etc.

Personal.—Dr. J. Earl Elsie, Pullman, has been elected delegate to the state medical society and Dr. William B. Palamountain, Colfax, alternate.——Dr. Elisha B. Schrock has resigned as a member of the staff of the Municipal Hospital, Seattle, and has been succeeded by Dr. J. M. Lea; Knoxville, Tenn.——Dr. James A. LaGasa, formerly Commissioner of Health of Tacoma, was operated on for appendicitis, May 4, and is reported to be doing well.

Tuberculosis Notes.—Two lots in the town of Glacier have been deeded to the Whatcom County Anti-Tuberculosis Society on which it is hoped that a sanatorium will be established in a short time.——The Everett Anti-Tuberculosis Society at its annual meeting elected Dr. Albert P. Duryee a director.——Whatcom County Anti-tuberculosis League was organized at Bellingham, April 28, and the following physicians were elected to office: President, Dr. Edward C. Ruge, Bellingham, and directors, Drs. Orville E. Beebe, Everson, and Spencer S. Howe, Lynden.

WYOMING

Will Prosecute Illegal Drug Sellers.—The State Board of Medical Examiners, at its quarterly meeting, adopted resolutions setting forth that hereafter it would revoke the certificate of any physician who violates the laws of the state by selling cocain or other drugs to drug addicts.

Personal.—Dr. F. Di Giacomia, Rock Springs, is said to have been adjudged insane and committed to the state hospital at Evanston.——Dr. Harry H. Ainsworth, Cody, who was operated on recently for appendicitis, is reported to be convalescent.——Dr. William A. Wyman has been elected president, Dr. George L. Strader, secretary, and Dr. Otto K. Snyder, treasurer, of the medical staff of St. John's Hospital, Cheyenne.

GENERAL NEWS AND COMMENT

Physicians of Virginia and the District Meet.—The medical societies of Northern Virginia and the District of Columbia, at their annual meeting in Manassas, Va., elected the following officers: Dr. A. Barnes Hooe, Washington, president; Dr. A. H. Coombs, Fairfax, Va., recording secretary; Dr. Charles S. White, Washington, corresponding-secretary, and Dr. Frederick M. Brooks, Fairfax, treasurer.

Southern Railway Surgeons Meet.—The fifteenth annual meeting of the Association of Surgeons of the Southern Railway was held in Richmond, May 24-26, under the presidency of Dr. Charles H. Starkel, Belleville, Ill. Among the interesting topics of discussion were the address of Surgeon Charles P. Wertenbaker, U. S. P. H. and M.-H. Service on "Sanitation of Railway Stations," and the paper of Dr. Henry T. Bahnson, Winston-Salem, on "Alcohol as a Dressing for Wounds." The Samuel Spencer Memorial Address was delivered by Dr. Lucien Lofton, North Emporia, Va. The Owen Bill calling for the establishment of a federal department of health was unanimously endorsed. Mobile was selected as the next meeting place. The following officers were elected: President, Dr. William C. Day, Danville, Va.; vice-presidents, Drs. H. J. Milliken, R. A. Smith, Hales Mill, Va.; Ambrose McCoy, Jackson, Tenn., and James P. Salb, Jasper, Ind.; secretary and treasurer, Dr. Jacob U. Ray, Woodstock, Ala., and member of the executive committee, Dr. Jay H. Durkee, Jacksonville, Fla.

Meeting of National Association for the Study and Prevention of Tuberculosis.—The sixth annual meeting of the above association, held in Washington May 2 and 3, was briefly reported in The Journal, May 14, page 1621. The resolution in regard to the pasteurization of milk placed the association on record as favoring clean milk and declaring that pasteurization is valuable where certified milk cannot be obtained, but that the process should be carefully supervised. The same resolution, however, declared that tuberculosis of the glands and lymph nodes in children, or other forms of tuberculosis are rarely caused by infection from bovine sources. Dr. William H. Park, of the New York Health Department, also showed in his paper that from a careful study of 400 cases of tuberculosis of all types chosen at randon, only 2.5 per cent. of tuberculosis in New York comes from infected milk, butter or meat, and this small percentage is found mainly in children and that tuberculosis in adults therefore comes from human beings. His conclusions were confirmed by about 500 cases studied in other parts of the world. Considerable interest was manifested in the paper of Dr. Lee K. Frankel, of New York, on the compulsory establishment of a fund from the wages of workmen to provide for their fellows who become afflicted with tuberculosis. Dr. Frankel believed this feasible and constitutional, but that a system of voluntary insurance would be impracticable. Dr. Livingston Farrand, executive secretary of the national association, reported that since May 1, 1909, the number of state and local antituberculosis associations has increased from 297 to 431, a gain of 134; the number of special dispensaries from 222 to 286; the number of sanatoriums and hospitals from 294 to 393, and the number of beds for tuberculosis cases from 15,244 to 22,720, a gain of 7,476. Eleven state legislatures in session since that time have enacted some law with reference to tuberculosis.

FOREIGN

Other Deaths in the Profession Abroad.—Besides the losses in the profession mentioned elsewhere, the death of the following eminent medical men should be recorded: E. van Beneden, professor of zoology at the university of Liège, Belgium, and founder and editor of the *Archives de Biologie*, noted for his important research on embryology, comparative anatomy and histology, president of the Belgian academy of sciences, corresponding member of five other academies, and recipient of honorary degrees from five British and German universities. His studies of hookworm disease and suggestions for prophylaxis were instrumental in stamping out the disease in the Belgian mines. The institute of zoology at Liège became under his guidance one of the foremost research laboratories of Europe.——E. L. V. Oedmannson, until recently professor of skin and venereal diseases at the university of Stockholm.——V. Mirbelli, professor of skin and venereal diseases at the university of Parma, Italy, one of the leaders in his specialty in Italy.——Although not a member of the medical profession, the death of S. Cannizzaro at the age of 84 may be mentioned in this connection, as his research on organic chemistry, the specific heat of elements, the distinction between atoms and molecules, his work on benzyl alcohol, etc., have aided in the solution of medical problems. He was professor of organic chemistry in the university of Rome and a senator of the realm.——C. Zanghello, an Italian physician, recently succumbed to bubonic plague at his post in the isolation hospital at Djeddah on the Red Sea, another victim to professional duty.

LONDON LETTER

(*From Our Regular Correspondent*)

LONDON, May 28, 1910.

The Study of Tropical Diseases

Sir Francis Lovell, dean of the London School of Tropical Medicine, has returned to this country after a tour extending over five months in the West Indies for the purpose of interesting those colonies in the work of the school and obtaining subsidies from them in aid of research work in tropical disease. He visited Barbados, the Windward and the Leeward Isles, Jamaica, Trinidad and British Guiana, at all of which places he was received cordially by the authorities and promised grants for the school. The total amount is about $2,500 a year for the next five years. Since its establishment ten years ago the school has trained 1,100 postgraduates in the study and investigation of tropical diseases. The income from fees and subscriptions is not sufficient to defray the cost of ordinary instruction, so that if research work is to be carried out on an adequate scale grants of some kind are necessary. The school has recently sent an expedition in charge of Dr. Bahr to Fiji to study tropical dysentery and another to Bagdad in charge of Dr. Wenyon to study "Delhi boil," which has been found to have some connection with kala-azar.

The Survival of Bedbugs

The length of time which bedbugs can survive without food is a point of practical importance. It has arisen in connection with the use of flock bedding made from filthy rags without disinfection. It was thought that, whatever its dangers, such flock would not contain living bugs as these animals were incapable of surviving many days without food. A correspondent of the *British Medical Journal*, Dr. W. Habgood, a health officer, has pointed out that this is not true. On having a house cleaned Sept. 1, 1909, he had 25 bugs collected in a clean bottle in which was placed a piece of clean white paper and clean calico. The mouth of the bottle was covered with a piece of clean calico. On October 26 all were alive. On Jan. 21, 1910, three or four old ones and one young one were alive. On February 26, nearly six months after capture, one large bug was running actively over the paper after the bottle had been warmed. The doctor's object in making the experiment was to find out whether the statement made by new tenants of a house that had been empty for months that bugs were there before their arrival was true.

The Development of Specialism

Like everything new the development of specialism in this very conservative country met with great opposition. Many specialties such as laryngology, proctology and genitourinary diseases were at first regarded with disfavor. They were long unrecognized by the large general hospitals and had to establish themselves at first in small hospitals built for the purpose. The force of events has proved too strong for the conservatives and also for the law of differentiation of advancing knowledge which evolutionists teach is being continually exemplified here as elsewhere. Still the suspicion with which specialists have been regarded has not wholly passed away. One of the most famous of the London hospitals—Guy's—has just made a remarkable advance in the recognition of specialism. The magnitude of the change will be appreciated by looking back on its history. Not until 1824, a century after its foundation, did any special department exist. In that year the ophthalmic department was created. In 1833 the electric department was established; in 1842 the obstetric department; in 1885 the throat department, and not until 1907 the orthopedic department. In this, as in many of the London hospitals, a general physician or surgeon might hold an appointment in the special department. Thus a general physician might be the dermatologist or a general surgeon the laryngologist. Now it has been decided to establish in Guy's Hospital a number of appointments which can be held only by specialists. These are to be appointed for diseases of the ear, throat, genitourinary organs and orthopedics. The reason is given that for the first three such special skill in the use of instruments is required for diagnosis and operations that it can hardly be expected in one who also practices general surgery. Special departments are also to be created for nervous diseases and diseases of children, but specialists are not necessary for these appointments, which may be held by general physicians. The beds of the hospital are to be rearranged so as to provide increased accommodation for these specialties.

Medical Entomology

The secretary of state for the colonies has appointed an "Entomological Research Committee" for tropical Africa for the purpose of organizing and coordinating the investigations of the numerous insects which from time immemorial have been the bane of that country. The committee is publishing a valuable periodical called the *Bulletin of Entomological Research*. Arrangements have been made by which the committee will be kept in touch with the organizations for the study of entomology that exist both to the north, in the Soudan and Egypt, and to the south in Rhodesia and the South African states. The number of known species of insects in tropical Africa has increased enormously. According to Dr. Shipley in 1830 the number of insects described and named was under 50,000; by 1881 it had risen to 220,000; now the number has reached 450,000 and thousands more await classification and description in collections deposited in museums, where no one has had time to work them out. It is calculated that the yet uncaptured species run into millions. To promote the work of sorting and studying the life-cycles of these insects two entomologists have been despatched, one to East Africa and the other to West Africa. They will instruct the residents, especially the government servants, in the methods of collecting and studying ticks and insects and of preserving them for transmission home. So far as is known many large genera, such as Lepidoptera and Neuroptera, exert but little influence on human affairs.

New X-Ray Department of the London Hospital

A new *x*-ray department has been completed at the London Hospital and is now in use. The most modern equipment has been provided and neither trouble nor expense has been spared. In 1899 the rays were first used therapeutically in the hospital for the treatment of lupus vulgaris. Since then many changes have been made. The old platinum hammer break and accumulator have been replaced by a copper rod and mercury bath transformer. The coils now used are much heavier and the quality of the x-ray tubes has been considerably improved. Formerly exposures were given by time, that is, for so many minutes. Now Sabouraud's pastilles are used. They are flat discs of platino-cyanid on cardboard. When exposed to the rays their bright green color turns first to yellow, then to orange, and finally to red. The pronounced orange color is called the "B dose" and is taken as the standard. This dose causes temporary epilation without permanent alopecia and does not produce dermatitis. Hence its value in the treatment of tinea tonsurans. In carcinoma stronger doses are given. Usually these are filtered through a sheet of aluminum or leather so as to allow the passage of only the higher rays, thus obtaining a deeper reaction and preventing dermatitis. There are four cubicles in the department, each fitted with a separate installation. The walls of these cubicles which reach from floor to ceiling, are made of lead and iron one-fourth inch thick, faced on both sides with pine. In these are windows of lead glass for observation purposes. This glass has been thoroughly tested and is impervious to the passage of the rays. The whole of the installation, except the controlling and driving gear, is inside the cubicle. When the patient and apparatus have been suitably arranged the operator comes outside the cubicle, shuts the door and switches on the current. Any movement or change of expression of the patient can at once be detected through the window. If the operator opens the door the current is stopped automatically. When the necessary number of revolutions of the motor have been made the current similarly stopped and an electric lamp over the cubicle is illuminated, thus attracting the operator's attention should he for the moment have been called to another part of the room. By these arrangements it is believed that the intractable dermatitis with its consecutive cancer from which so many operators have suffered will be prevented. The number of patients treated daily in the department amounts to from 35 to 40.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, May 20, 1910.

Admission of Foreigners to the Concours of the Externship and Internship of Hospitals

Unlike certain other countries where foreigners not infrequently occupy university chairs, France does not permit foreigners to hold any post, no matter how modest, bestowed by the national government. The apparent exceptions presented by the positions of hospital extern and intern are accounted for by the fact that these places are bestowed, not by the national government, but by the Public Charities or the municipalities. The bestowal of these positions, however, has aroused protest recently. The question has just been discussed in the Réunion médico-chirurgicale des hôpitaux de Bordeaux. The society wisely admitted that the great number of the candidates enrolled for the concours of the externship and internship of hospitals must stimulate the zeal of all the competitors; that, moreover, an admission of foreign students would serve to disseminate the renown of French medical science in all parts of the world; and that, consequently, the higher patriotism would authorize this admission.

The Suppression of Fraud in Foods

In order to suppress fraud and to guarantee to producers and to honest retail dealers the protection which they deserve, the minister of agriculture has just taken two interesting measures. In the first place, each year at the end of November, there are to be collected at the mayor's office of each wine-growing commune two series of samples of the wines of that harvest. The first series is to be reserved for the departments of agriculture and finance, which cooperate in the suppression of frauds; the second is for the use of the judicial tribunals, in the expert examinations which may be ordered. Thus wines which are under suspicion may at any time be compared with authentic samples. The second innovation has to do with dealers in foodstuffs, who often have trouble through unwittingly selling adulterated foodstuffs. Hereafter the commercial organizations may nominate, subject to the approval of the prefect, an agent paid by themselves who, on requisition of the members, will take samples out of goods on their arrival at the transportation terminal. These samples, to the number of four, are to be ticketed, sealed, registered and deposited in a place designated by the association. If, later on, foodstuffs which are below standard are seized at the retail dealers, comparison with the samples will clear up the question of culpability.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, May 19, 1910.

Personals

At the annual meeting of the German laryngologic society a few days ago, the prize founded on the occasion of the seventieth birthday of Prof. B. Fraenkel, was awarded for the first time; it was given to Professor Killian of Freiburg for his notable work in laryngology.

The Siebel prize, given by the Senckenberg foundation in Frankfort a. M. for the best work on children's diseases or embryology published in the last four years, has been awarded to the Berlin pediatrist, Professor Finkelstein, for his investigations on alimentary intoxication.

Women Students

The number of women attending the Prussian universities in 1910 has risen to 2,824 as compared with 1,680 in 1908-09. The women students in the medical department numbered 266 as opposed to 188 in 1908-09.

The Number of Lepers

The number of lepers in the German empire at the end of 1909 amounted to 23 (1908: 25), of whom 18 were in Prussia, 4 at Hamburg, and 1 in Bavaria.

The Campaign Against Mosquitoes

As the destruction of the larvæ of mosquitoes in water can not be accomplished on certain lakes and ponds by the use of petroleum or the establishment of drainage on account of the cost, it is recommended by a ministerial decree, based on research by Professor Schilling in the institute of infectious diseases, to encourage the increase of the natural enemies of the mosquito larvæ. The so-called water beetle (the *dyticus*, *nepa* and *notonecta* species), the stickleback (*Gasterosteus*), the small water salamander (*Triton taeniatus*) and the larvæ of dragon flies are the best destroyers of mosquito larvæ. It is recommended to protect the enemies of the mosquito and to introduce them in pools where they are not present, especially during the winter. It is also important to destroy the mosquitoes which are hibernating during the winter. As mosquitoes in the beginning of winter resort to the cellar, stable, etc., and cling to the walls and ceiling, they can easily be smoked out of their resting places and killed with a good insect powder.

Museum for Infant Hygiene in Munich

The headquarters for the care of infants in Bavaria contemplates the establishment of a permanent museum for infant hygiene. The government has made the first contribution of $360 (1,500 marks) and has placed rooms at its disposal. The museum which will be the first of its kind in Germany is for the purpose of spreading information regarding the need and the prospects of the fight against the excessive infantile mortality among the lower classes of the population. The museum is to be simple and adapted to the common people and so organized that parts of it can be transported to other parts of Bavaria as traveling expositions or to illustrate lectures. The various departments comprise (1) infant hygiene, (2) the extent and causes of infant mortality, (3) the development, structure and function of the infant's body, (4) infantile nutrition, (5) care of infants, (6) children's diseases, (7) vaccination, (8) milk, (9) public and private care.

Mothers' Home at Hamburg

The Hamburg league for the protection of mothers contemplates the foundation of a small home for mothers, especially with the aid of a small legacy of $12,000 (50,000 marks) that has fallen to it. The home is to possess at most 20 beds. It will be limited to economic aid and not serve like the home in Bremen for charitable purposes. For instance, the three months' gratuitous care of mother and child as is the custom in Bremen will not be provided for, but the mother will be given the opportunity to earn her way by the provision of sewing, washing and similar work. Homeless pregnant women, for the most part illegitimate mothers, are received. Delivery will occur in the hospital. After dismissal from the hospitals which takes place twelve days after delivery, puerperal women in need of convalescent care will be received into the home for mothers. The price for bed and room is 8 cents (30 pfennigs), for board 12 cents (50 pfennigs) per day. Each woman must furnish her own crib.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, May 23, 1910.

Housing of the Poor

To provide cheap and healthful housing for the poor, a law has been passed in Austria which authorizes the government to devote a sum of 6,000,000 kronen (about $1,500,000) every year from 1910 till 1920 for the purpose of giving loans free from all duties and interest to such building-societies as will erect small lodging-houses. The idea has been much agitated by the Society for Prevention of Tuberculosis. The management of the fund mentioned above will be in the hands of a joint committee, selected by the government and the society. Special regulations will be imposed on the building companies. Each room will have to contain at least 30 cubic meters of air-space per person living in it. No back yard will be allowed of less than 6 meters' depth, thus giving a clear space of 12 meters (13½ yards) between two back windows of opposite houses. The houses will be two stories high. Up-to-date water-closets, kitchens, and arrangements for dust-removal are also required. The latter point is especially well worth mentioning, for it is a constant outcry of the hygienic authorities in this city that the present mode of removing household refuse here is shamefully primitive. No home work except domestic household labor and light sewing will be allowed in these lodgings. Playgrounds for children, kept free from dust, are also to be provided. It is intended to give the loans in the first place for the relief of the population in Vienna, Prague, Graz and a few industrial cities where tuberculosis is present.

The First Fight Between Practitioners and Krankenkasse

Owing to the "social reform" bill which threatens the profession with very severe losses of the material whence to obtain private practice, a preliminary trial has been made to see whether the organization of our profession is efficient enough for the coming events. In industrial towns in Lower Austria, differences of opinion as regards remuneration of clubwork, as well as to the eligibility of a member to the club, prompted the practitioners to refuse all work for the *Krankenkasse*. The patients were informed that they would be treated at reduced rates, but not on behalf of the *Kasse*. The managing board of the club (*Kasse*) tried in vain to obtain the services of other doctors; the medical organization proved effective and thus the club had to make its terms with the practitioners. It was agreed that, in future, appointments of doctors will be negotiated through the medical council, thus insuring uniform rates of payment and recognition of the right of the practitioner to apply against orders of the board of the club to the Council. The result of this fight shows that if the social reform bill should become law the profession has it in its power to turn it into a weapon for its own good.

Pharmacology

[Contribution from the Chemical Laboratory of the American Medical Association.]

HYMOSA

W. A. Puckner and W. S. Hilpert

Frequent requests for information regarding the composition of hymosa, manufactured by the Walker Pharmacal Co., St. Louis, and a perusal of the extensive and nostrum-like advertising the product is receiving, made the chemical examination of the preparation seem desirable. If the label is to be believed, hymosa has been of use in "acute and chronic muscular and articular rheumatism, gout, sciatica, lumbago, pleurodynia and neuralgia, whether due to uric acid diathesis or not . . . "

The composition of hymosa as given by the proprietors is set forth in the following statement:

> ". . . Hymosa, in which the remedies Frangula, Actea Spicata, Stellaria Media, Franciscea Uniflora, Rhus Toxicodendron, Passiflora Incarnata, Phytolacca Decandra and Echinacea Angustifolia are combined in the proportions which experience has shown will obtain the quickest and best results without any of the stomach and heart complications so often following the administration of salicylic acid."
>
> "Contains no Salicylic Acid."

Thus the explicit statement is made that hymosa contains certain vegetable drugs (most of them obsolete and valueless) and that it does not contain salicylic acid. By inference the claim repeatedly is made that the nostrum does not contain any salicylates.

> ". . . Hymosa has achieved most remarkable results in overcoming rheumatism in cases where salicylates have been tried in vain . . ."
>
> "Salicylic acid was not successful in this case of rheumatism of the stomach."
>
> "Negative results from salicylates—Hymosa cures."
>
> ". . . the salicylates didn't help? Then we must try Hymosa."

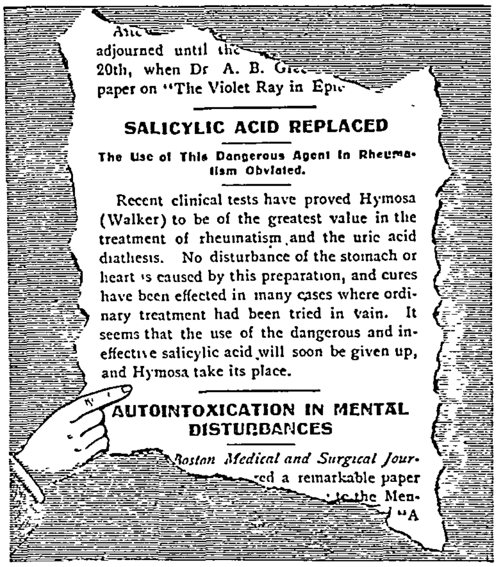
Still harping on the undesirability of salicylates and the value of hymosa the advertising pamphlets state:

> "Salicylic Acid Replaced. The Use of This Dangerous Agent in Rheumatism Obviated."
>
> "It seems that the use of the dangerous and ineffective salicylic acid will soon be given up and hymosa take its place."
>
> "Former methods of treating rheumatism . . . have been very unsatisfactory . . . because of the heart and stomach difficulties brought on by salicylates of which most rheumatism remedies are composed."
>
> "Could not tolerate the salicylates."

Finally in a letter issued to physicians we are told:

> ". . . you will find hymosa to possess prompt and positive curative action with the additional advantage of avoiding the heart and stomach complications, which the salicylates too often cause."

It is evident from the above quotations, in which the salicylates are denounced specifically or by implication, and from the label which states that no salicylic acid is present, that the exploiters of the nostrum deliberately intended to give the impression that hymosa is free from salicylates or salicylic acid and contains only the vegetable or plant drugs enumerated. The very fact that the proprietors make such repeated efforts to give the impression that hymosa is free from salicylates is in itself sufficient to arouse suspicion and hence in the examination particular attention was given to the detection of salicylic acid or salicylates with the following results:



adjourned until th
20th, when Dr A. B. Gr
paper on "The Violet Ray in Ep

SALICYLIC ACID REPLACED

The Use of This Dangerous Agent in Rheumatism Obviated.

Recent clinical tests have proved Hymosa (Walker) to be of the greatest value in the treatment of rheumatism and the uric acid diathesis. No disturbance of the stomach or heart is caused by this preparation, and cures have been effected in many cases where ordinary treatment had been tried in vain. It seems that the use of the dangerous and ineffective salicylic acid will soon be given up, and Hymosa take its place.

AUTOINTOXICATION IN MENTAL DISTURBANCES

Boston Medical and Surgical Jour-
ed a remarkable paper
to the Men-
"A

Reproduction (reduced) of an advertisement of Hymosa. This indicates the attempt made to convey, by implication, the idea that the salicylates are absent from Hymosa.

> *Examination.*—Hymosa as purchased on the market is a dark brown liquid with an odor of sassafras and a rather sweetish taste, reacting acid to litmus. Qualitative tests having indicated the presence of salicylate, iodid, sodium, potassium, alcohol and some organic matter, presumably sugars and some plant extractives, these were determined

quantitatively.[1] It was found that a part of the salicylate was present as free salicylic acid and part *in a combined* form. The sodium determinations indicated that all the salicylate, excepting that in the form of free salicylic acid, was present as sodium salicylate. From the results of the potassium estimations, it was evident that the iodin was present in the form of potassium iodid.

From the results of the analysis it is believed that the preparation has approximately the following composition:

Salicylic Acid	0.32 gm.
Sodium Salicylate	1.15 gm.
Potassium Iodid	0.32 gm.
Sugars and extractives	4.60 gm.
Alcohol, U. S. P.	16.86 c.c.
Water to make	100.00 c.c.

These results indicate that hymosa is essentially a solution containing salicylic acid, sodium salicylate, potassium iodid, alcohol, sugars and plant extractives in the proportions given above, and show that the various statements referred to, regarding the absence of salicylic acid and salicylates are misleading and untrue. It further illustrates the repeatedly demonstrated fact that nostrums exploited as wonderful and new discoveries are new in name only—and whatever therapeutic value they possess depends on old and tried medicinal agents.

Editorial Note: In describing the methods employed by the manufacturers of Manola in exploiting their product, attention was called to the fact that the Manola Company was reported as being a subsidiary affair of the Luyties Homeopathic Pharmacy Company of St. Louis. It is reported that this same company also operates the Walker Pharmacal Company, which exploits hymosa and pas-avena.

REVISION OF THE PHARMACOPEIA

Report of the Committee of the Section on Dermatology

INDICATION OF EXTERNAL DOSAGE

We respectfully offer the following suggestions:

Articles in the Pharmacopeia which are used externally should, we believe, have indicated the strength in which they are used externally as well as their internal doses. For example:

Boric Acid.—Strength for external use as well as doses should be mentioned.

Carbon Dioxid.—This should be in Pharmacopeia and mention should be made of its use as a freezing agent.

Picric Acid.—This should be in Pharmacopeia and strength for use in burns given.

Salicylic Acid.—Strength for external use should be given, say from 2 per cent. in ointment base as antiseptic, up to 20 or 25 per cent. as caustic.

Sulphurous Acid.—Mention should be made of external use in skin diseases.

Tannic Acid.—Some indication of external use should be given.

Silver Nitrate.—Indication that it is a caustic should be given.

Arsenic Trioxid.—Its use as a caustic and its dosage should be indicated.

Balsam of Peru.—Its external use should be indicated.

Bismuth Subnitrate.—Its external use should be indicated.

Cantharis.—Its external use and dosage should be mentioned.

Guaiacol.—Its external use and dosage should be mentioned.

Mercuric Chlorid.—Use as antiseptic and caustic should be mentioned and strength of solutions given.

Oleum Cadini.—Strength for external use should be given.

Pix Liquida.—Strength for external use should be given.

Pyrogallol.—External use and dosage should be mentioned.

Resorcinol.—External use and dosage should be mentioned.

Sulphur.—External use and dosage should be mentioned.

Zinc Chlorid.—External use as caustic should be mentioned.

SUBSTANCES RECOMMENDED TO BE ADDED

Adeps anserini (goose grease) should be added.

Liquor guttæ perchæ should be added.

Chaulmoogra oil should be added and its internal and external dosage given.

Some additional salts of mercury, from the many now in use, especially in the treatment of syphilis, should be added. We suggest as eligible salts the following: benzoate, cyanid, salicylate, succinimid. These are among those most frequently used for hypodermic medication.

Liquor alumini acetatis is a much-used preparation in dermatology which might well be added to the Pharmacopeia.

Potassa sulphurata, much used in dermatology, should be added and its external dosage given.

There should be some powder in the Pharmacopeia of brownish pink tinge with which to make external applications of flesh color. Calamine is widely used for that purpose now and because of its wide use it is the most eligible powder for this purpose. The objection to calamine is that it is not standardized. We would suggest that if possible some standard color or composition for calamine should be adopted and that it be added to the Pharmacopeia. Zinc oxid, if properly colored, would be a better powder than calamine because it is lighter. A powder of the proper pinkish tint can be made by the addition of 0.3 per cent. of jeweler's rouge. The addition of this or some other artificially colored powder might possibly be made to the Pharmacopeia as a standard flesh-colored powder. It is necessary that the pigment in such a powder be insoluble in ordinary solvents.

Coal-tar (pix carbonis) should have official recognition.

A soluble, non-irritating salt of arsenic for hypodermic use should be given in the Pharmacopeia. Sodium cacodylate seems the most eligible.

The soft soap of the Pharmacopeia is not a good soap for therapeutic use because of its disagreeable odor of linseed oil. There should be an official soft soap made with olive oil or cotton-seed oil which would avoid this disagreeable odor.

The same objection to the odor of soft soap made with linseed oil holds against the present linimentum saponis mollis and if an olive oil or cotton-seed oil soft soap could be adopted in the Pharmacopeia it should be used in making the liniment of soft soap for therapeutic purposes.

The name "tincture of green soap" as a synonym of "linimentum saponis mollis" should be given in the Pharmacopeia because of its almost universal use.

Emplastrum acidi salicylici 10 per cent. is used in dermatology and might well be made official.

SUBSTANCES RECOMMENDED TO BE DROPPED OR REDUCED

The various forms of external applications used by dermatologists are well covered in the Pharmacopeia and National Formulary. Many local applications are included which dermatologists do not use but the dropping of which we do not deem it proper to recommend because of their possible use in other departments of medicine.

In general we find little use for the mixed ointments containing active ingredients, as there is the same objection to their use that obtains against all ready-made prescriptions. As a rule the proportions of active ingredients in the official ointments are stronger than these medicaments are commonly used in dermatology.

Unguentum hydrargyri dilutum should be dropped. It is confused with 50 per cent. mercury ointment; and the preparation of dilute mercury ointments from the 50 per cent. ointment is so easy that the dilute official ointment is of no use.

Unguentum hydrargyri nitratis, 10 per cent., is too strong; a better preparation would be 5 per cent.

Unguentum hydrargyri oxidi flavi, 10 per cent., is too strong; a better ointment would be 5 per cent.

Unguentum hydrargyri oxidi rubri, 10 per cent., is too strong; a better one would be 5 per cent.

Unguentum picis liquidæ, 50 per cent., is very much too strong. It should be reduced to at least 20 per cent.

Unguentum potassi iodidi should be dropped.

Unguentum sulphuris, 15 per cent., is too strong. It should not be more than 10 per cent.

---

[1] The details of the analysis will be sent on receipt of a stamped, addressed envelope; they will also be published in the annual report of the Chemical Laboratory.

Unguentum zinci stearatis, 50 per cent., is, so far as we know, not used by dermatologists and we know no reason of its inclusion in the Pharmacopeia.

Of the cerates, ceratum is a good base, though we know no reason why it should not as well be made with white petrolatum 70 per cent. or benzoinated lard 70 per cent., instead of white petrolatum 20 per cent., and benzoinated lard 50 per cent.

The other cerates in the Pharmacopeia have practically no use in dermatology.

Unguentum is a satisfactory base.

Of the medicated plasters, emplastrum plumbi and emplastrum hydrargyri are the only ones which have any use in dermatology.

Correspondence

Age and Exercise

To the Editor:—You were kind enough to publish (Aug. 28, 1909, p. 730) a letter from me on the subject above cited, in which I took strong ground in favor of the proposition that "most men lie down and die, not knowing what they are capable of, either mentally or physically." This letter had been called out, you may remember, by an editorial of yours under the title "The Septuagenarian Pedestrian" which, of course, referred to Mr. Weston and his walk from New York to San Francisco. I thought when I wrote you, nine months ago, that perhaps sometime I should try to demonstrate in my own body the truth of my assertions. Accordingly, a week ago last Thursday (May 12, 1910), I set out to walk from Newark, N. J., to Philadelphia, intending to accomplish the feat in twenty-four hours if possible. I lost my way during the night, and by so doing, added several miles to the walk, so that I calculated that in twenty-two hours I had walked over ninety miles, when I reached the city line of Philadelphia. In two months from to-morrow I shall be 59 years old. The principal reason for undertaking the walk was that I wished to demonstrate experimentally that people over middle age can improve their physical condition as well as their mental powers, as they grow older, if they really wish to do so. Mr. Weston's career goes a long way in support of the above assertion. He walked from Portland, Maine, to Chicago in 1907 in sixteen and one-half hours' less time than it had taken to accomplish the same feat forty years before.

The walk that he has just completed from Los Angeles to New York is not only the greatest feat of its kind on record; but far better than Mr. Weston ever did or was capable of doing in the earlier years of his life. So far from this man finding himself broken down and ready to die at 70 years of age, he seems to be capable of doing more than he ever could have done before.

Now why is this? Is it a miracle or a reversion of Nature? Or is there some fake about it? The answer is very plain and simple. It is merely a case in which a man has gradually developed great powers of physical endurance and has conserved them by abstinence from liquor and tobacco and by great moderation in diet. So firmly convinced was I that nearly any one could effect a similar improvement in his powers by following a similar regimen that I determined to try some experiments on myself. I had stopped the use of tobacco and all forms of alcoholic drink some years ago, and since I have been eating whole wheat bread and bran bread my general health and my powers of endurance have notably improved. For twenty years before beginning to eat whole wheat products I was so constipated that my bowels never moved without medicine. When I began to have natural movements again I began to feel like a different man, so much brighter and more cheerful and more ready for work or for play. I could not help observing that my capacity for all sorts of prolonged exertion had greatly augmented.

Finally, to put the matter to the test, I determined on an endurance walk for twenty-four hours and chose the journey from Newark to Philadelphia as a good test. That I was able to accomplish this feat at my age with only some stiffness of the muscles and some blisters, I attribute entirely to my diet and my abstemious habits, added to the fact that I am and always have been a staunch advocate of walking as a wholesome and delightful pastime.

Yet I have never before attempted an endurance test of any description. Now I feel so elated over the success of my first attempt that I may start out again some time to see what I can do, and when I am as old as Mr. Weston I may perhaps have improved as much over my present walking capacity as he has improved in the last twelve years. It is quite needless for people to give up doing anything that is to be done because they are approaching 70. That is really the age when they should be in their prime mentally and physically.

Most people who have accomplished anything worth while have worked long after they were 70. Yet the sad part of the matter is that they—at least many of them—have been obliged to do their work in spite of bodily weakness and the so-called infirmities of age, whereas had they known how to take care of their bodies and followed out my simple rules of life, they would have enjoyed their work at 70 as much as they did at 50.

As Parkes said years ago, "our fate is in our own hands," and it is because I am trying to teach people that truth that I am so much pleased that I have been able to demonstrate it, in great part at least, in my own case; for people will, I hope, now begin to believe that I know whereof I speak.

Richard Cole Newton, Montclair N. J.

Hypertension and Treatment

To the Editor:—From my standpoint, the medical profession is much indebted practically to Dr. Miller's article in the last issue of The Journal.[*] The prevailing fashion nowadays is, so soon as hypertension is revealed, either by palpation of the radial or by means of the finger and the sphygmomanometer, to recur to medication of an active sort to neutralize the condition, and this is done not only when there are unpleasant or it may be threatening symptoms, but also when those that exist are of very mild type, or, indeed, none is present. The condition is there and that is all. It has been clear to me and others for a long while, that hypertension may be a wholly conservative process, and on that account should not be interfered with, except for good and sufficient reasons, and then only in a judicious and temporary way. Again, it is also evident that the cause of symptoms is not always simple, but rather a combination of factors which require close attention to interpret correctly. To medicate actively before one understands fully what one is doing is not useful. For my part I am satisfied that harm has been done by too great reliance on the mere reading of the sphygmomanometer. Many things should be considered before the height of the column of mercury becomes a reliable guide as to treatment. It is not essential, however, for the attending physician to be an expert in the application of the instrument in order to give it proper interpretation, but it is necessary that the instrument should be properly used. This is manifest in the same way that is true of the ophthalmoscope or laryngoscope. It is also true now of many laboratory researches in hospital or consulting room, which are made with special instruments.

Beverley Robinson, New York.

Rare Fetal Monstrosity

To the Editor:—In The Journal, May 28, 1910, page 1786, is a report of a case of "Rare Fetal Monstrosity" by Dr. Aranow, in which he says he has found but one case reported in medical literature of "entire absence of abdominal parietes" in a new-born child. I call attention to a case reported by me in *American Medicine*, vol. ii, page 208, the case being almost identical with the one mentioned by Dr. Aranow, the chief difference being that in my case there was entire absence of sexual organs and anal aperture.

H. H. Loveland, M.D., Republic, Mich.

Table of Contents Misleading in Its Reference to Chinosol

To the Editor:—In The Journal, May 28, containing the report on Chinosol by the Council on Pharmacy and Chemistry, the table of contents (second cover page) is so worded as to have caused an entirely incorrect interpretation. The report of the Council states that Chinosol is *non-poisonous and that* it is an intensely powerful antiseptic, much stronger than phenol (carbolic acid) and even stronger than bichlorid. It is as an antiseptic that we are introducing Chinosol; thus as a matter of justice to Chinosol and to us, we ask that you publish this letter.

The Chinosol Co., New York City,
by Charles Roome Parmele, President.

Warning Against an Impostor

To the Editor:—A man pretending to be my brother is traveling through the south and west borrowing money from physicians. If you can warn the profession against such an impostor you would, I am sure, be doing a public service.

L. Emmett Holt, New York.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Delaware: Regular, Dover, June 21; Homeopathic, Wilmington, June 21. Secretary of the Medical Council, Dr. Henry W. Briggs, Wilmington.

Kansas: Scottish Rite Temple, Kansas City, June 14. Sec., Dr. F. P. Hatfield, Olathe.

Maryland: 1211 Cathedral St., Baltimore, June 15. Sec., Dr. J. Mc.P. Scott, Hagerstown.

Minnesota: State University Laboratories, Minneapolis, June 14-17. Sec., Dr. W. S. Fullerton, American National Bank Bldg., St. Paul.

Missouri: St. Louis and Kansas City, June 13-15. Sec., Dr. Frank B. Hiller, Jefferson City.

New Jersey: State House, Trenton, June 21. Sec., Dr. H. G. Norton.

New York: Albany, June 28-July 1. Chief of Examinations Division, Mr. Charles F. Wheelock, Albany.

North Carolina: Wrightsville, June 15. Sec., Dr. Benjamin K. Hays, Oxford.

Pennsylvania: Regular, Philadelphia and Pittsburg, June 21; Homeopathic, Philadelphia, June 21; Eclectic, Harrisburg, June 21. Secretary of the Medical Council, Mr. Nathan C. Schaeffer, Harrisburg.

Ohio: Columbus, June 13-15. Sec., Dr. George H. Matson, State House.

South Carolina: State House, Columbia, June 14. Sec., Dr. Harry H. Wyman, Aiken.

Texas: House of Representatives, Austin, June 28-30. Sec., Dr. M. E. Daniel, Honey Grove.

Virginia: Richmond, June 21-24. Sec., Dr. R. S. Martin, Stuart.

Wyoming: Laramie, June 22-24. Sec., Dr. S. B. Miller.

Wisconsin January Report

Dr. John M. Beffel, secretary of the Wisconsin State Board of Medical Examiners reports the written examination held at Milwaukee, Jan. 12-15, 1910. The number of subjects examined in was 21; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 16, of whom 14 passed, including 1 *osteopath*, 1 failed and 1 was conditioned. Twenty-six candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
College of Physicians and Surgeons, Chicago	(1909)	80
Northwestern University Medical School	(1909)	79
Hamline University	(1909)	87
Jefferson Medical College	(1909)	84
Marquette University	(1908) 75, 77; (1909)	75, 75, 77, 78
Wisconsin College of Physician and Surgeons	(1909)	82
McGill University, Canada	(1909)	89
University of Heidelberg, Germany	(1905)	85

FAILED

Marquette University	(1909)*	

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
George Washington University	(1905)	Maryland
Northwestern Univ. M. School (2, 1904) (1907)	(1908)	Illinois

University of Iowa, College of Medicine	(1890)	Iowa
College of Physicians and Surgeons, Baltimore	(1908)	Virginia
Johns Hopkins University	(1908)	Maryland
St. Louis University	(2, 1908)	Illinois
Woman's Medical College of Pennsylvania	(1908)	Maryland
Wisconsin College of Phys. and Surgeons	(1897)	Iowa
University of Toronto, Canada	(1909)	Iowa

* Percentage not given.

Connecticut March Report

Dr. Charles A. Tuttle, secretary of the Connecticut Medical Examining Board, reports the written examination held at New Haven, March 8-9, 1910. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 19, *of whom 14 passed and 4 failed and 1 withdrew*. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Yale Medical School	(1908) 81.9; (1909)	79.7, 84.8, 89.3
Georgetown University	(1907) 81.9; (1908)	78, 81.3
Johns Hopkins University	(1906)	84.5
Harvard Medical School	(1903)	75.8
Dartmouth Medical School	(1909)	85.3
Cornell University Medical College	(1905)	87.3
Long Island College Hospital	(1907)	83.7
Jefferson Medical College	(1909)	75.8
University College of Medicine, Richmond	(1903)	78

FAILED

Howard University	(1909)	69
Baltimore Medical College	(1909)	68.5, 68.9, 71

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

PROPHYLACTIC USE OF ANTITETANIC SERUM

To the Editor:—Please publish a list of articles on the use of antitetanic serum as a prophylactic measure, with names of authors.

H. J. Scherck, St. Louis.

Answer.—The following articles deal with this subject:

Scherck: *Therapeutic Gazette*, November, 1904.

Anders, J. M., and Morgan, A. C.: Tetanus, The Journal A. M. A., July 29, 1905, p. 314.

Wiedemann, A.: Serotherapy of Tetanus, *München. med. Wchnschr.*, April 12, 1910; abstr. in The Journal A. M. A., May 21, 1910, p. 1731.

HAIRY TONGUE

To the Editor:—In THE JOURNAL, July 24, 1909, p. 324, is a short abstract (No. 81, Arrowsmith, H.: *Laryngoscope*, July, 1909) on black hairy tongue, or glossitis nigra, which, however, does not speak of the treatment. Please give me any information or references available on the pathology and treatment of the condition.

HARRY S. BULL, Auburn, N. Y.

ANSWER.—Hairy tongue is a rare affection, consisting of an overgrowth of the epithelium covering the filiform papillæ, forming a growth that closely resembles tendrils, lashes, seaweed or hairs, and has been in some cases compared to feathers. The hypertrophied epidermis is colored dark brown or black, the coloring being variously attributed to colors produced by mold or other micro-organisms or to staining of the epithelium, sometimes intentionally in the case of hysterical patients. No symptoms are usually produced beyond a mawkish taste and occasionally pains. In Curtis' case the pain was quite pronounced. The condition may persist for a variable time, but as a rule eventually disappears spontaneously. Treatment seems to be of little avail. The patch may be painted with 2 per cent. salicylic acid or with diluted lactic acid; or a solution of phenol, 1 in 60, may be rubbed in with a clean piece of cloth, three or four times a day. Reference may be made to Butlin ("Diseases of the Tongue," p. 145), Stelwagon ("Diseases of the Skin," Edition 5, p. 1119) and Pusey ("Principles and Practice of Dermatology," Edition 1, p. 996). The latter authors give full bibliographies. Blegvad (*Ann. Otol., Rhinol. and Laryngol.*, September, 1908, p. 753) has an exhaustive article on the subject with bibliography.

METHOD OF ESTIMATING THE AMMONIA COEFFICIENT OF URINE

To the Editor:—Dr. Adam H. Wright, of the University of Toronto, speaking about pernicious vomiting of pregnancy, (THE JOURNAL, May 7, 1910, p. 1503), refers to Dr. Whitridge Williams of Baltimore, as having demonstrated, by chemical examination of the urine, a "decrease in the amount of nitrogen excreted as urea, and an increase in the amount excreted as ammonia." Can you refer me to a description of these chemical tests? G. N. P.

ANSWER:—Briefly speaking, the method which has generally been used in Toronto for the estimation of the ammonia coefficient may be described as follows: (1) estimation of the total nitrogen by Kjeldahl's method; (2) estimation of ammonia by Folin's method; and (3) division of ammonia nitrogen by total nitrogen to get the ammonia coefficient. It is difficult to carry out the Kjeldahl method in an ordinary office, but Prof. J. B. Leathes, of the Department of Pathological Chemistry, University of Toronto, has simplified the process to such an extent that any physician may use it. Professor Leathes estimates the ammonia nitrogen by a method introduced by Ronchèse and Malfatin about two years ago, which takes less time than Folin's method. Dr. F. W. Rolph furnishes the following description of the methods now used in the laboratory of the University of Toronto:

The combustion of the nitrogenous substances in urine and the conversion of this nitrogen into ammonium sulphate by the action of strong sulphuric acid can be accurately effected if a smaller quantity than that usually prescribed is taken, in a test-tube, in any room without any inconvenience if the following arrangements are made:

With a pipette exactly 1 c.c. of the urine is introduced into a test-tube made of Jena glass, or some other equally resistant glass. Two or three times this volume of strong, pure sulphuric acid is added, and a few milligrams of copper sulphate or copper wire. The tube is then set in a holder obliquely over a small Bunsen flame, and an inverted flask is held over the mouth of the tube by another holder fixed to the same stand. This flask contains 1 or 2 c.c. of strong caustic alkali solution and the inside of the flask has been moistened all around with this alkali. The flask can be kept cool by placing on it a piece of wet filter-paper, and by keeping the paper moist by means of a siphon thread leading from a vessel of water. The strongly acid and offensive fumes that are given off from the mouth of the test-tube may in this way be completely condensed in the flask, and absorbed by the alkali without any escape into the air of the room. The combustion is usually finished in about twenty minutes, and the amount of ammonia found can be determined either by distillation or a current of air as usually done.

The formalin method of estimation of ammonia nitrogen introduced by Ronchèse, Malfatin and others is as follows:

Take 20 c.c. of urine. Dilute with water and add some crystals of neutral potassium oxalate and a few drops of alcoholic solution of phenolphthalein. Titrate with decinormal caustic soda until a definite red tinge appears. Now add to the urine 2 c.c. of previously neutralized commercial formalin. In a few seconds the pink coloration of the mixture disappears. This is due to the fact that the ammonia present in the urine combined with acids has united as a condensation reaction with formaldehyd as hexamethylenamin. Thus the acid which was previously combined with this ammonia base has been set free, causing the disappearance of the pink color. Further titration is now carried out with the same decinormal caustic soda solution, until the pink color reappears.

Each cubic centimeter of decinormal soda used in this second titration represents 0.0014 gm. of nitrogen in the form of ammonia.

EXAMPLE.—Amount of urine in 24 hours = 1500 c.c.

No. of c.c. of n/10 soda used in 2d. titration = 8.

20 c.c. of urine were used for testing.

$\therefore 8/20 \times 1500/1 \times .0014/1 = 0.84$ gm. of ammonia nitrogen in 24 hours.

Or if we want to find the amount of ammonia nitrogen in 100 c.c.

$8/20 \times 100/1 \times 0.0014/1 = .056$.

Now if the total nitrogen were 15 gm.

The nitrogen in 1500 c.c. urine would be 15 gm.

The nitrogen in 1 c.c. urine would be 15/1500

The nitrogen in 100 c.c. urine would be $15 \times 100/1500 = 1$ gm.

$\therefore$ the ammonia nitrogen would be to the total nitrogen as 5.6 to 100

$\therefore$ ammonia coefficient = 5.6.

The Public Service

Medical Department, U. S. Army

Changes for the week ended June 4, 1910:

[illegible] ot., detailed for duty in the Bureau of [illegible] ands.

[illegible] Deane C., majors, detailed to represent the Medical Department of the Army at the meeting of the American Medical Association at St. Louis, Mo., June 7-10, 1910.

Van Poole, Gideon McD., capt., detailed as chief surgeon during the military tournament at Chicago, during the month of July, 1910.

Owen, Leartus J., capt., detailed as sanitary officer during the military tournament at Chicago, during the month of July 1910.

Casaday, George H., dental surgeon, relieved from temporary duty at Fort Rosecrans, Cal., and to return to Presidio of Monterey, Cal., for duty; when his services are no longer needed at the latter post, will stand relieved and will proceed to Army General Hospital, San Francisco, Cal., for duty.

Napier, Edward L., 1st lieut., M. R. C., granted 10 days' leave of absence.

Casaday, George H., dental surgeon, left from duty at Fort Rosecrans, Cal., en route to Army General Hospital, San Francisco, Cal., for duty.

The following named officers of the Medical Reserve Corps, having completed course at Army Medical School, have been ordered to stations designated: Casper, Joseph, 1st lieut., Du Pont, Del., Dept. of the East; Sheep, William L., 1st lieut., Ethan Allan, Vt., Dept. of the East; Davis, William C., 1st lieut., Ethan Allen, Vt., Dept. of the East; Knox, Howard A., 1st lieut., Fort Hancock, N. J., Dept. of the East; Beeuwkes, Henry, 1st lieut., Fort Jay, N. Y., Dept. of the East; Crum, Wayne H., 1st lieut., Madison Barracks, N. Y., Dept. of the East; Carr, William B., 1st lieut., Fort Monroe, Va., Dept. of the East; Holmes, Robert W., 1st lieut., Plattsburg Barracks, N. Y., Dept. of the East; Darby, Taylor E., 1st lieut., Fort McPherson, Ga., Dept. of the Gulf; Davis, Arthur O., 1st lieut., Fort Oglethorpe, Ga., Dept. of Gulf; Beery, Harry R., 1st lieut., Fort Benjamin Harrison, Ind., Dept. of the Lakes; Mount, James R., 1st lieut., Fort Sheridan, Ill., Dept. of the Lakes; Demmer, Charles C., 1st lieut., Fort Thomas, Ky., Dept. of the Lakes; Bowen, Albert S., 1st lieut., Fort Snelling, Minn., Dept. of Dakota; Etter, Harry B., 1st lieut., Fort Snelling, Minn., Dept. of Dakota; Fisk, Owen C., 1st lieut., Fort Crooke, Neb., Dept. of Missouri; Fletcher, John P., 1st lieut., Fort D. A Russell, Wyo., Dept. of Missouri; Ferenbaugh, Thomas L., 1st lieut., Fort Des Moines, Iowa; Dept. of Missouri; Burket, John A., 1st lieut., Fort Riley, Kan., Dept. of Missouri; Kramer, Floyd, 1st lieut., Fo [illegible] of Missouri; Fox, James S., 1st lieut., Fort [illegible] t. of Texas; Aydelotte, John T., 1st lieut., [illegible] Dept. of Texas, relieving First Lieutena [illegible] Cook, George W., 1st lieut., Fort Douglas [illegible]; Johnson, Thomas H., 1st lieut., Fort Baker, Cal., Dept. of California; King, Charles T., 1st lieut., Presidio of Monterey, Cal., Dept. of California; Holmberg, Carl E., 1st lieut., Presidio of San Francisco, Cal., Dept. of California; Kremers, Edward D., 1st lieut., Presidio of San Francisco, Cal., Dept. of California; Hill, Felix R., 1st lieut., Fort George Wright, Wash., Dept. of the Columbia [illegible] D., 1st lieut., Vancouver Barracks, Wash., De [illegible] McCornack, Condon C., 1st lieut., Vancouver [illegible] of the Columbia; DeVoe, Ralph G., 1st lieut. [illegible], Dept. of the Columbia; Jones, Edgar C., 1st lieut., Fort Liscum, Alaska. Dept. of the Columbia, relieving Captain John A. Clark, Medical Corps; Allen William H., 1st lieut., Fort Slocum, N. Y.; Jones, Glenn I., 1st lieut., Fort McDowell, Cal.; Weed, Mark D., 1st lieut., Walter Reed General Hospital, Takoma Park, D. C.; McAlee, Larry B., 1st lieut., Army and Navy General Hospital, Hot Springs, Ark.; Welles, Edward M., Jr., 1st lieut., Army General Hospital, San Francisco, Cal.; Napier Edward L., 1st lieut., Army General Hospital, San Francisco, Cal.; Reynolds, Royal, 1st lieut., Co. B, Hospital Corps, Presidio, San Francisco; Austin, Thomas C., 1st lieut., Co. B, Hospital Corps, Presidio, San Francisco; Bastion, Joseph E., 1st lieut., Co. C, Hospital Corps, Walter Reed General Hospital, District of Columbia; Schlanser, Adam E., 1st lieut., Co. C, Hospital Corps, Walter Reed General Hospital, District of Columbia; Cooper, Wibb E., 1st lieut., Fort D. A. Russell, Wyo., Dept. of the Missouri; Haverkampf, Charles W., 1st lieut., Co. A, Hospital Corps, Fort D. A. Russell, Wyo., Dept. of the Missouri; Edwards, George M., 1st lieut., West Point, N. Y.

Coffey, Albion McD., 1st lieut., M. R. C., when relieved from Fort Sam Houston, Tex., will proceed to Fort St. Philip, La., relieving First Lieutenant Samuel A. Springwater, M. R. C., who will proceed to his home and report arrival to The Adjutant General.

Clark, John A., Major, M. C., when relieved from duty at Fort Liscum, Alaska, to proceed to Seattle, Wash., and report arrival to The Adjutant General.

Koerper, Conrad E., M. C., major, relieved from Fort Slocum, N. Y., on arrival of First Lieutenant William H. Allen, M. R. C., and ordered to Fort Bayard, N. Mex., relieving Major Charles N. Barney, M. C., ordered to Fort Wadsworth, N. Y.

Dawe, Courtlandt W., M. R. C., ordered from Plattsburg Barracks, N. Y., to home; report arrival to The Adjutant General.

Persons, Elbert E., M. C., major, and Nichols, Henry J., capt., M. C., appointed members of retiring board at Governor's Island, N. Y.

Banister, John M., col., M. C., ordered to U. S. Military Prison. Fort Leavenworth, Kan., on official business and on completion to return to his proper station.

Austin, Thomas C., 1st lieut., M. R. C., granted 10 days' leave, effective on or about June 1, 1910.

Fuller, Leigh A., M. C., granted 10 days' leave of absence, effective June 3, 1910.

Graham, George D., dental surgeon, returned to Fort Leavenworth, Kan., from duty at Fort Des Moines, Iowa.

Medical Corps, U. S. Navy

Changes for the week ended June 4, 1910:

Stibbens, F. H., P. A. surgeon, commissioned passed assistant surgeon from Jan. 4, 1910.

Allen, A. H., P. A. surgeon, detached from the Naval Hospital, New York, and ordered to duty at the Navy Yard, Boston, Mass., in connection with Navy rifle team.

Pugh, W. E., Jr., P. A. surgeon, ordered to duty at the Naval Hospital, New York.

U. S. Public Health and Marine-Hospital Service

Changes for the week ended June 1, 1910:

Cofer, L. E.: asst.-surgeon-general, granted 3 days' leave of absence from May 26, 1910; directed to proceed to Reedy Island Quarantine Station on special temporary duty.

Association News

NEW MEMBERS

List of new members of the American Medical Association for the month of May, 1910:

ALABAMA

Baird, R. H., Cullman.
Dawson, J. R., Birmingham.
Jones, R. C., Mobile.
Ward, D. W., Tuscaloosa.

ARKANSAS

Cooksey, W. P., Atlanta.
Drummond, R. M., Russellville.
Early, C. S., Camden.
Evans, L. T., Barren Fork.
Gilbrech, A. H., Clarendon.
Howton, Oleander, Osceola.
Kelly, J. L., Hope.
Philp, W. H., St. Francis.
Summers, D. C., Elm Springs.

CALIFORNIA

Chaffin, R. C., Los Angeles.
Clarke, W. T., Los Angeles.
Forline, Hamilton, Redlands.
Greene, Frances M., Berkeley.
McKenney, A. C., San Francisco.
Newman, W. H., Long Beach.
Russell, P. N., Fresno.
Taylor, A. H., San Francisco.

COLORADO

Burnett, N. M., Lamar.
Campbell, W. H., Pueblo.

CONNECTICUT

Tuch, Morris, Hartford.

FLORIDA

Hurchinson, Clarence, Pensacola.
Rivers, T. M., Kissimmee.
Gaskins, J. D., Jacksonville.

GEORGIA

Gibbs, E. T., Gainesville.
Joyner, A. S., Sylvania.
Kennedy, W. D., Metter.

ILLINOIS

Ash, J. C., La Harpe.
Bailey, H. B., Rockford.
Bartholomew, E. K., Chicago.
Burns, W. I., Witt.
Chapman, W. D., Silvis.
Cohen, Hyman, Chicago.
Curtis, A. H., Chicago.
Dewey, Grace, Jacksonville.
Dattelzweig, M. F., Chicago.
Drake, C. St. Clair, Chicago.
Fitzpatrick, E. H., Pontiac.
Glasen, G. M., Chicago.
Grayson, W. F., Granite City.
Green, J. A., Rockford.
Griffeth, F. W., Elgin.
Gunn, J. C., Belleville.

Harlan, N. R., Freeport.
Harris, Monroe, Newton.
[illegible] Chicago.
[illegible]
[illegible]
Kleckner, R. E., Mattoon.
Koch, W. A., Middletown.
Liston, J. B., Shipman.
Massey, C. V., Chicago.
Moldenhauer, William J., Chicago.
Motley, E. G., Virden.
Nason, W. C., Ashkum.
Neal, J. R., Springfield.
Nyman, C. V., Rockford.
Perry, W. H., Sterling.
Seely, W. J., Red Bud.
Spyker, J. H., Decatur.
Steely, G. W., Louisville.
Thomas, E. H., Argenta.
Tonney, F. O., Chicago.
Vanatta, H. B., Lerna.
Vermeren, C., Chicago.
Wells, J. W., Waltonville.
Wetherla, W. W., Chicago.
Von Zelinski, W. F., Chicago.

INDIANA

Brown, K. T., Crawfordsville.
Cain, D. B., Evansville.
Charles, Etta, Summitville.
Dobyns, P. K., Franklin.
Dow, W. S., Indianapolis.
Harold, A. R., Indianapolis.
Harold, N. E., *Indianapolis.*
King, W. F., Columbia City.
Markley, W. H., Pennville.
Prather, S. A., Vincennes.
Reed, J. H., Logansport.
Rice, T. R., Petersburg.
Simonds, J. P., Indianapolis.
Terry, O. P., Lafayette.
Thomas, E. C., Indianapolis.

IOWA

Anspach, R. G., Colfax.
Besser, E. F., Newton.
Crary, A. W., Boone.
Earl, H. D., Cherokee.
Grimwood, W. H., Ft. Madison.
Patterson, A. W., Linden.

KANSAS

Battendieri, O. D., Pittsburg.
Billings, A. E., Topeka.
Burk, F. O., Iowa City.
Everhardy, J. L., Leavenworth.
Meyer, Grant, Lincolnville.
Moore, R. W., Arcadia.
Navem, H. A., Argentine.
Philipp, Herman, Wichita.
Ratliff, H. S., Cawker.
Reed, E. W., Holton.
Risdon, J. W., Leavenworth.
Schrader, L. M., Kinsley.
Wolfe, R. D., Council Grove.
Young, R. C., Arkansas City.
Zinke, S. G., Leavenworth.

KENTUCKY

Behrman, Michael, Covington.
Brummett, U. G., Middlesboro.
Eckler, C. M., Williamstown.
Goodloe, E. R., Little Cypress.
Gossett, W. L., Franklin.
Hopson, J. L., Cadiz.
Jones, R. M., Calvert City.
Langolf, F. A., Louisville.
Lukins, J. B., Louisville.
McEuen, H. B., St. Charles.
Offutt, W. N., Lexington.
Stone, T. W., Bowling Green.
Wahle, A. J., Louisville.
Woodburn, J. C., Bremen.

LOUISIANA

Adams, J. M., St. Joseph.
Hargrove, M. V., Oakdale.
Ledoux, A., New Orleans.
Lilly, J. G., St. Joseph.
Trahan, A. R., Lafayette.

MARYLAND

Gombel, William, Baltimore.
Laroque, H. E., Baltimore.

MASSACHUSETTS

Adamion, P. A., Boston.
Bieberbach, W. D., Worcester.
Crawford, F. W., S. Weymouth.
Shaw, J. W., Newburyport.

MICHIGAN

Arminen, K. V., Hancock.
Collins, W. E., Kalamazoo.
Force, W. H., Ludington.
Johnson, R. K., Detroit.
Kriekard, P. J., Grand Rapids.
Linn, R. S., Detroit.
Repp, W. A., Detroit.
Stone, Harriette M., Kalamazoo.

MINNESOTA

Field, Merton, Minnesota Lake.
Norman, J. F., Crookston.
Olsen, S. H., Milaca.
Ratcliffe, J. J., Aitkin.
Rogers, G. M. F., Austin.

MISSISSIPPI

Barnes, I. F., Gulfport.
Johnson, G. E., Hudsonville.
Keithly, C. L., Rome.
McLean, E. R., Cleveland.

MISSOURI

Aldridge, M. R., Jefferson City.
Armstrong, C. L., Webster Groves.
Ash, O. O., Moberly.
Baker, J. H. P., Salisbury.
Baker, Marshall, Webster Groves.
Barger, J. N., Albany.
Barker, W. S., St. Louis.
Barnhart, D. A., Huntsville.
Baumgartner, C., St. Louis.
Bell, E. T., Columbia.
Bellaire, R. F., St. Louis.
Bentele, Elizabeth, St. Louis.
Biewend, E. F., St. Louis.
Boyd, F. R., St. Louis.
Cameron, Solon, St. Louis.
Coil, P. E., Mexico.
Dalgliesh, G. D., Rockville.
Dames, A. F., St. Louis.
Davis, F. L., St. Louis.
Douglas, J. T., Ferguson.
Doyle, J. M., St. Joseph.
Drace, J. J., Kennett.
Dreyfus, J. W., Louisiana.
Dutton, C. K., Moberly.
Elkins, W. H., Crystal City.
Evans, E. E., Columbia.
Evans, R. L., Boonville.
Evers, E. T., St. Louis.
Ewing, F. C., St. Louis.
Fischer, O. F., St. Louis.
Frank, Konrad, St. Louis.
Gaertner, C. W., St. Louis.
Ginsberg, E. L., Kansas City.
Gove, H. S., Linn.
Greensfelder, Harry, Kirkwood.
Gundlach, Arthur, St. Louis.
Habermaas, Albert, St. Louis.
Haffner, E. L., Hermann.
Hall, Elizabeth L., Carthage.
Hardaway, W. A., St. Louis.
Hardy, Joseph, St. Louis.
Hawkins, W. R., Glasgow.
Hawley, T. S., St. Louis.
Heuman, G. W., St. Louis.
Hewitt, W. R., St. Louis.
Hill, J. A., Jefferson City.
Hoberecht, C. A., St. Louis.
Horst, O. C., St. Louis.
Hughes, M. R., St. Louis.
Hulen, J. C., Centralia.
Hurt, P. L., Boonville.
Janes, V. B., Cameron.
Johnson, G. A., Moberly.
Juengel, A. H., St. Louis.
Kampschmidt, A. W., Columbia.
Kempff, L. A., St. Louis.
Kesl, G. M., St. Louis.
Koch, O. W., Ballwin.
Larew, J. T., St. Louis.
Lewis, M. D., Columbia.
Magoon, F. L., St. Louis.
Martin, C. P., St. Louis.
McCall, G. D., Fulton.
McCormick, F. L., *Huntsville.*
Murray, S. A., Holden.
Musser, C. W., Metz.
Newman, Percy, St. Louis.
Niebruegge, H. J., St. Louis.
Norris, W. A., Columbia.
Owen, H. I., Fulton.
Paulin, Stanley, Kansas City.
Porth, J. P., Jefferson City.
Rodes, W. R., Mexico.
Rothwell, C. A., Mexico.
Rotteck, Julius, St. Louis.
Scholz, Phil., St. Louis.
Sewing, A. H., St. Louis.
Sharp, W. L., Little Rock.
Shumate, D. L., Kansas City.
Stewart, E. L., Kansas City.
Storrs, H. J., St. Louis.
Stevens, C. D., St. Louis.
Toalson, G. F., Mexico.
Torrance, L. B., St. Louis.
Walker, R. A., St. Louis.
Weinsberg, J. H., St. Louis.
Wilson, R. E., La Belle.
Wright, U. S., Fayette.
Yost, W. B., St. Louis.
Young, D. H., Fulton.

MONTANA

Phillips, O. S., Browning.

NEBRASKA

Langstaff, G. A., Blair.
Myers, B. L., Omaha.
Phillipsen, J. A., Lincoln.
Raines, R. F., Red Cloud.

NEVADA

Adams, A. F., Ely.

NEW HAMPSHIRE

Burtt, E. D., Lincoln.
Howland, Clifford, Bradford.

NEW JERSEY

Dougherty, A. C., Newark.
Flynn, T. H., Somerville.
Foster, G. H., Rockaway.
Miller, H. G., Millville.
Muttart, G. W., Jersey City.
Reid, J. W., Kearny.
Runyon, L. P., New Brunswick.
Winslow, J. H., Vineland.

NEW MEXICO

Dillon, A. L., Clovis.

NEW YORK

Anthony, H. E., Moravia.
Brown, H. W., Binghamton.
Brown, Sherman, *Kings Park.*
Burns, G. S., Rochester.
Carter, DeLancy, New York City.
Crisman, B. J., Utica.
Elmendorf, TenEyck, New York City.
Fincke, H. S., Astoria.
Held, R. J., New York City.
Hoobler, B. R., *New Cork City.*
Lustig, Emil, Buffalo.
Meyer, W. H., New York City.
Nash, P. I., *Coney Island.*
Prince, Howard, Byron.
Teeter, L. H., Niagara Falls.
Wilson, R. C., Ithaca.

NORTH CAROLINA

von Ruck, Silvio, Asheville.

NORTH DAKOTA

Brugman, F. A., Minot.
Macdonald, A. W., Valley City.
Sorenson, A. R., Barton.

OHIO

Batte, J. T., Cincinnati.
Blakey, H. B., Columbus.
Cox, E. H., Cleveland.
Griffin, J. G., *Kelleys Island.*
List, W. E., Cincinnati.
Morrison, F. A., Uhrichsville.
Paul, C. M., Cincinnati.
Roop, W. O., Dayton.
Samson, F. B., Cincinnati.
Smith, W. L., Toledo.
Spicer, D. M., Cleveland.
Wendelken, C. W., Portsmouth.
Williams, J. H., Cincinnati.
Workman, I. S., Gambier.

OKLAHOMA

Armstrong, D., Mead.
Coppedge, O. S., Depew.
Henderson, C. F., Chant.
Lewis, J. L., *Lawton.*
Lockett, B. L., Swink.
Long, Dock, Duncan.
McBurney, C. H., *Clinton.*
Overton, L. M., Guthrie.
Pope, A. J., Hanna.
Reeder, H. M., Asher.
Robinson, E. T., Cleveland.

PROCEEDINGS OF THE ST. LOUIS SESSION

MINUTES OF THE SIXTY-FIRST ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ST. LOUIS, MO., JUNE 6-10, 1910

House of Delegates

First Meeting — Monday Morning, June 6

The House of Delegates convened in the auditorium of the St. Louis Medical Society at 10:35 a. m., and was called to order by the President, Dr. William C. Gorgas, Ancon, Panama.

Dr. H. Bert Ellis, California, presented a preliminary report of the Committee on Credentials, as chairman.

There being no objection raised, the report of the committee was accepted.

The General Secretary called the roll, and 74 members responded.

The President: The next order is the reading, correction and adoption of the minutes of the Sixtieth Annual Session.

Dr. Alexander R. Craig, Pennsylvania: I move that the minutes as printed be approved.

This motion was seconded and carried.

President's Address

To the Members of the House of Delegates of the American Medical Association:

It is customary for the retiring President to make suggestions to the House of Delegates looking to the betterment of the Association. The more or less close contact with the affairs of the Association for the preceding two years should place him in an advantageous position for doing this.

The Association is developing so steadily and running so successfully that I see very little room for suggestion as to change.

During the year the question was raised as to the power of our President, under our constitution, to fill vacancies that may occur in the standing committees during the interim between meetings of the House of Delegates. The matter was referred to our legal adviser. He was not clear in his own mind as to whether the President had the authority or not. I recommend that the matter be authoritatively settled.

The Association is doing a very extensive and good work and is extending its usefulness in many directions, but it seems to me that there is a tendency to take up new work and drop out of sight work already in hand. This, I think, should be borne in mind.

It is probable that most of our members attend these meetings attracted by the scientific phase, which is mostly developed in the Sections. This is a most important part of our work and should be encouraged in every way.

Our constitution says that one of the objects of our Associatino is to safeguard the material interests of the medical profession in the country at large. This phase of our work has come to the front in the last few years through our Council on Pharmacy and Chemistry. This work has been most far-reaching in protecting the people at large against all sorts of patent nostrums. As an Association we have made bitter enemies of the people engaged in the "patent-medicine" business and as they command large capital they are at present making a serious organized fight against us. This is the most altruistic part of our activity for the benefit of others or for the members of the Assoication.

Our Association is probably the most compactly organized body of men in the whole country; its branches are located in every part of the country. Through the county and state society we can reach all national legislators. This gives us great influence on legislation. During the past year our Committee on Medical Legislation has been very active and successful in shaping national legislation. This work is good and should be pushed, but as the Association feels its enlarging powers in this direction care should be taken that we do not become involved in political matters. From this time forward there will be more or less tendency to complication in this direction.

The address was referred to the Reference Committee on Reports of Officers.

Report of the General Secretary

To the Members of the House of Delegates of the American Medical Association:

I submit herewith a report for the year 1909-1910:

Membership

The membership of the American Medical Association on May 1, 1909, as shown by the report for that year was 33,935. During the past year 289 members have died, 1,937 have resigned, 625 have been dropped as not eligible, 406 have been dropped for non-payment of dues, and 95 have been removed from the rolls on account of being reported as "not found" or on account of mail returned by the Postoffice Department, making a total of 3,352 names to be deducted from the membership list. Since May 1, 1909, there have been added 3,593 names to the membership list, of which 2,628 were transferred from the subscription list, and 965 were new members. The membership of the American Medical Association on May 1, 1910, was 34,176, a net gain for the year of 241. The explanation of the apparently large number of members entered as resigned is that many who were not eligible under the by-laws were allowed to resign in preference to being entered as dropped, while many others resigned on account of age.

Committees Appointed Ad Interim

Since your last meeting, on June 11, 1909, the following committees were appointed by the president:

SELECTION OF INSIGNIA FOR THE A. M. A.

Maj. M. W. Ireland, chairman, Washington, D. C.; G. L. Taneyhill, Baltimore, Md.; C. E. Cantrell, Greenville, Texas; Samuel P. Gerhard, Philadelphia, Pa.; Samuel Wolfe, Philadelphia, Pa.

COMMITTEE ON ESTABLISHMENT OF PHYSICIANS' SANITARIUM

Edward Jackson, chairman, Denver, Colo.; A. C. Magruder, Colorado Springs, Colo.; Jefferson R. Kean, Washington, D. C.; A. T. Bristow, Brooklyn, N. Y.; H. Bert Ellis, Los Angeles, Cal.

DELEGATES TO CONVENTION ON REVISION OF PHARMACOPEIA

J. A. Capps, Chicago; George H. Simmons, Chicago; W. A. Puckner, Chicago.

Application from the Medical Association of the Isthmian Canal Zone

In the fall of 1909 an application for recognition and affiliation was received from the Medical Association of the Isthmian Canal Zone. The application, together with the accompanying documents, is referred to the House of Delegates for consideration and action, with the recommendation that it be accepted and that the Medical Association of the Isthmian Canal Zone be recognized as one of the constituent associations of the American Medical Association.

Death of Dr. Burrell

A year ago Dr. Herbert Leslie Burrell was President of the American Medical Association, and should have presided over the deliberations of the House of Delegates during the first day of the annual session. Illness, however, prevented his attendance at that meeting. Dr. Burrell did not recover from that illness and died April 27, 1910. During the year he had been unable to attend to any of his professional or college duties. Dr. Burrell was 54 years of age. In his death the Association has lost a distinguished member and a valuable officer; American surgery a skilful exponent; and the medical profession, one who has always been ready to do his duty as he saw it.

Membership of State Associations

The membership of the various constituent state associations, according to the records in the General Secretary's office on May 1, 1910, is as follows:

Alabama	1,738	New Hampshire	594
Arizona	131	New. Jersey	1,340
Arkansas	989	New Mexico	237
California	2,057	New York	6,755
Colorado	811	North Carolina	1,141
Connecticut	803	North Dakota	376
Delaware	108	Ohio	3,934
Dist. of Columbia	548	Oklahoma	1,309
Florida	339	Oregon	391
Georgia	1,145	Pennsylvania	5,351
Idaho	116	Rhode Island	367
Illinois	5,404	South Carolina	740
Indiana	2,550	South Dakota	341
Iowa	2,081	Tennessee	1,253
Kansas	1,376	Texas	3,080
Kentucky	1,986	Utah	210
Louisiana	1,068	Vermont	398
Maine	574	Virginia	1,604
Maryland	1,107	Washington	870
Massachusetts	3,303	West Virginia	971
Michigan	2,300	Wisconsin	1,730
Minnesota	1,220	Wyoming	123
Mississippi	1,001	Hawaii	58
Missouri	2,862	Philippine Islands	95
Montana	201		
Nebraska	1,001	Total	70,146
Nevada	59		

UNIFORM REGULATION OF MEMBERSHIP

The second report of the Committee on Uniform Regulation of Membership, which was enlarged at Atlantic City by the addition of five state secretaries, will be presented by that committee. The regulation of the details of individual membership is becoming more and more important to the county and state societies, as well as to the American Medical Association, and the uniform, systematic and equitable regulation of membership affairs is deserving of careful attention.

THE SECRETARYSHIP—A BIT OF HISTORY

Dr. W. B. Atkinson, my immediate predecessor, was elected permanent secretary in 1864. The office was regarded as a permanent one, as the title indicates. For several years preceding 1898 there had been considerable criticism regarding the conduct of the office—whether just or not is immaterial—and this resulted in definite action by the Association at the Denver meeting, 1898. That year certain resolutions, relative to the matter, were introduced, among which were the following:

> "*Resolved,* That a General Secretary be appointed by the Business Committee at a salary not exceeding $3,000 per year, who, under the direction of the Business Committee, shall forward the interests of the Association in every way possible.
>
> "*Resolved,* That the Business Committee be directed to consider the matter and report to the Association in regard to the feasibility of the plan proposed."

The Business Committee, on the following day, reported:

> "While the Committee fully agree as to the desirability of having much more active secretary work done for the Association, and believe that the plan proposed would greatly increase the scope and usefulness of the Association, it is not prepared at the moment to recommend the adoption of the resolution. It is a matter of such very great importance that further consideration of the details involved is necessary, and as it may possibly involve a change in the Constitution and By-Laws, your Committee has decided to recommend that the matter lie over for one year, and hereby gives notice that it proposes such changes, if any are necessary, in the Constitution and By-Laws at the next annual meeting of the Association."

Later, as the matter involved the expenditure of money, it was referred to the Trustees to report the following year. The Business Committee also submitted an amendment to the By-Laws, providing for the annual election of a Secretary.

At the Columbus meeting, 1899, the matter came before the Association in three ways; from the committee to which the proposed amendment of the By-Laws had been referred; from the Board of Trustees; and from the President, Dr. J. M. Mathews, in the annual President's address. I quote from the latter:

> "For several years there has been a heated debate, if not wrangle, at each annual meeting, in general session, over the secretaryship. This is both unseemly and undignified, and is to be much deplored. It seems to me that there is an easy solution to this matter. Let the editor of our Journal be the secretary of the Association. The Board of Trustees has wisely insisted that he devote his whole time to the Journal. It does, therefore, appear that the secretaryship should be one of his duties. By so acting he is brought into a closer relation with the business management of the Association and with the active membership of the same. He would himself be responsible for a correct report of all proceedings, and be enabled to keep them without fault. The question whether or not any addition should be made to his salary for this additional work can be determined by the board of trustees. Our present secretary has served us long and well, and for his services in the past the Association should, and no doubt does, feel deeply obligated to him. I am sure that he would be the first to acquiesce in any move that would enhance the business interests or the prosperity of the Association. I therefore very respectfully offer the suggestion as above stated."

The Committee's recommendations regarding the change of By-Laws and the recommendations of the Trustees were formulated into amendments to the By-Laws, among which was the following:

> "Each officer, except the Secretary, shall hold office for one year, and until his successor is selected. The Editor of the JOURNAL of the American Medical Association shall be the Secretary of this Association, and shall serve as such without additional compensation."

Two years later, in 1901, at my suggestion, the first "shall" in the second sentence above quoted was changed to "may," again placing the election of General Secretary in the hands of the Association, and later all mention of the connection between the two offices was eliminated from the By-Laws.

Thus, in 1899, being editor of THE JOURNAL, against my wishes and under protest I became the secretary. Having accepted the position I tried to perform what I considered the duties pertaining to the office. The work increased rapidly, and within two years I found that I was devoting nearly as much time and energy to the secretarial as to THE JOURNAL work.

About six years ago I suggested to the Board of Trustees that I relinquish the secretaryship on account of the amount of detail work connected therewith. The Board of Trustees, however, advised against this, but recommended and authorized the employment of an assistant to the secretary whose duty should be to look after and carry out the details of that work. After some time spent in looking for a man fitted for the place, the position was tendered to Dr. F. R. Green who accepted it, and in April, 1905, assumed the duties of Assistant to the General Secretary. Since that time he has been taking care of most of the secretarial work.

However, I had decided not to hold the office for longer than ten years, and last year, 1909, fully expected to ask you to elect some one else. For reasons not necessary to mention, I did not do so.

I think the time has come, however, when I should ask you to relieve me of the responsibilities of the office of General Secretary, and this I now do. I realize that it is not usual to refuse a thing, especially an elective office, before it is offered. I think it better, however, to make the announcement now, so that there may be ample time for you to consider carefully whom you shall select for the position.

I want to take this opportunity of thanking you for the kindness, cooperation and assistance that I have received at your hands. Eleven consecutive years I have been unanimously elected General Secretary, twice at the General Meeting before the reorganization, and nine times by the House of Delegates.

During this time much has been accomplished. For only a minor part of what has been done can I claim any credit, but what little may have been accomplished through my efforts was made possible because a host of splendid men in our profession have loyally and unselfishly given their support and cooperation to the work.

Respectfully submitted. GEORGE H. SIMMONS,
General Secretary.

This report, on motion, was referred to the Reference Committee on Reports of Officers.

Report of the Board of Trustees

To the Members of the House of Delegates of the American Medical Association:

The progress made by this Association during the past year has been most encouraging. Anyone who read the elaborate and instructive reports presented by the permanent Committees and Councils to this body at its meeting a year ago, could not fail to be impressed by the earnest, hard work done by these Committees and by the great value of that work to the profession as well as to the people.

As these Committees report directly to this body your Board of Trustees refrains from presenting the details of their work for the past year, but recommends to your careful study and consideration their forthcoming reports, feeling certain that the members of these Committees who do this work at great sacrifice of time, energy and often money will receive at your hands the earnest encouragement and hearty approbation which they deserve.

It is one of the most encouraging features of our organization that men of the character of those forming these Committees will so generously give of their time and labor for the benefit of all.

In looking over these reports one is struck by the numerous lines along which the activities of the Association are extending. Instead of a small body of men meeting once a year for scientific and social purposes we now find a vast organization extending into every county and almost every town in the land deeply engaged not only in the scientific work of the profession but also in the solution of economic and sociologic problems in a manner scarcely dreamed of by the most enthusiastic worker but a few years ago.

Among the numerous subjects which the organization has taken up may be mentioned: The systematic and thorough investigation of the medical teaching institutions of the United States, with a view to elevating the standard of medical education and the moral and scientific attainments of those who seek to enter the profession.

The careful study of the various state laws governing the practice of medicine with a view to the drafting of a uniform medical practice act which shall secure to the people the greatest degree of protection and to the profession the greatest justice:

The systematic education of the people in matters relating to both public and personal hygiene, to the prevention of blindness, to the care of dependents, to the prevention of the propogation of the insane and of the criminal, etc.:

The passage of such laws by the national and state governments as shall secure to the people pure, wholesome food and pure drugs:

The establishment of a National Department of Health with powers and duties commensurate with the importance of the subject:

The adoption of a uniform system of nomenclature and classification of diseases:

The careful study of the rules and regulations governing membership in county and state societies with a view to securing greater uniformity thereof and for the purpose of improving if possible the plan of organization of the local, state and national bodies:

The education of the people in regard to the dangers of the patent medicine frauds and of the profession in regard to the composition and the effects of the proprietary drugs, new remedies, etc.

These are by no means all of the problems which the Association is undertaking but they are sufficient to indicate the various lines along which its activities are extending, and while the Board of Trustees wishes it distinctly understood that it is in accord with all of these movements, yet it cannot refrain from uttering a word of caution against attempting too many things at a time lest we dissipate our energies and forces in a multiplicity of aims.

As the Council on Pharmacy and Chemistry reports to the Board of Trustees, a few words concerning the work done by this Council during the past year may be of interest.

The amount of work done has greatly exceeded that of any previous year and the results of the work as published from week to week in THE JOURNAL have been of the greatest practical value to every physician. In support of this statement we wish to mention briefly the work done by the Council in the examination of the numerous so-called meat extracts and meat juices with which the market, both public and professional, has been flooded.

It will be acknowledged by all that the nourishing of the sick is a subject of the most vital importance and therefore, any product for which the manufacturer claims unusual nutritive value should have its worth carefully determined by competent judges.

After a most exhaustive examination of these products it was found that the meat extracts are practically devoid of nutritive bodies and that while some of the meat juices were shown to contain considerable amounts of bodies of great food value, many of the products on the market which were claimed to be meat juices proved to be nothing but meat extracts or similar non-assimilable products.

Since the prescribing of such products by physicians, under the mistaken idea that they possess food value, must result in harm to the patients, the Council investigated those most widely advertised and published its findings in THE JOURNAL so that no physician need be misled any longer by the erroneous claims made by the manufacturer for any of these products.

Another class of products of great interest and importance at this time and concerning which reliable information has been difficult to obtain is that of the various serums and vaccines.

During the past year the Council has done a most timely piece of work in this direction and has prepared and published descriptions of the several products as they are found on the American market.

These two classes are mentioned, as they are somewhat out of the ordinary, simply to illustrate the character of the work which the Council is doing. That the magnificent work done by the Council is receiving just recognition beyond the confines of our own land is well shown by the fact that during the past year a number of prominent European firms have taken active measures to have all of their products listed by the Council.

One of these firms has opened a branch office in this country because it found that the drug firm which had acted as its representative was also engaged in the exploitation of patent medicines. The submission of products by the foreign firms demonstrates that the listing of new products with New and Nonofficial Remedies is being felt essential as an indication of good faith with the profession.

It may be stated that the Council has examined practically all the non-official articles now on the market and that those not listed by it are deemed by it unworthy of consideration by the profession.

In the main the work of the Council thus far has been to determine whether or not those dealing in medicines were telling the truth.

This work really should have been done by the federal, state and municipal authorities but it required the courage of those who constitute the Council and the prestige of the American Medical Association to antagonize the powerful interests connected with proprietary medicines.

The amount of work done in the Chemical Laboratory in our own building has increased greatly so that it is impossible to even mention all of the products and compounds which have been investigated during the past year.

It seems almost unbelievable that any person or firm would attempt to perpetrate such gross frauds on the profession and the people as have been uncovered in our own laboratory.

For instance a product called "Health Grains" which is offered as a remedy for dyspepsia, indigestion, nervousness, etc., was found to consist of nearly 90 per cent. sand and about 10 per cent. sugar.

Another product sold at an exorbitant price with outrageously exaggerated claims as a face preparation, was found to be about 90 per cent. ordinary Epsom salts and 10 per cent. borax.

A certain product which was submitted to the Council by the manufacturer was found not to contain the substances specified on the label. When attention was called to the fact the manufacturer attempted to explain the discrepancy between the label and the contents by saying it was due to a lack of coordination between the various departments. Remember this was not a patent medicine but a proprietary article offered to and used by the physician. The name of the manufacturer has been withheld because the article has been taken off the market.

Numerous other incidents similar to the above might be mentioned but sufficient has been said to indicate the character of the work done in the laboratory.

Your Board of Trustees desires to bring to your attention at this time a matter of great importance, and in doing so it does not wish to be understood as attempting to anticipate the report nor in any way to interfere with the prerogatives of the special committee appointed by you to consider the advisability of consolidating certain of the present committees, but it wishes to call your attention to the fact that in your earnest endeavor to bring about certain very desirable results you have appointed perhaps unconsciously, a multiplicity of committees whose duties so overlap in many directions as to lead to an unnecessary duplication of the work with a concomitant duplication of expense and loss of energy, and a lack of cooperation and concurrence among the committees renders negative or ineffectual much of the work undertaken.

It will be recalled that those Committees which have been centralized have been productive of the best results. It is therefore believed that if the various Committees which now exist with a similarity of duties were centralized in a single Bureau with a paid secretary and stenographer with headquarters in THE JOURNAL building much more effective work would be done and greater results accomplished.

This does not in any sense mean that fewer individuals would be engaged in the work, as the Bureau should have the power to establish any number of sub-committees to carry on the work along special lines, but it means simply this, that there would be a head to systematize and correlate the work of the various sub-committees.

Closely related to this subject is that of the Women's Committees on Public Educational Matters.

It may be well to state at the outset that the Board of Trustees is in entire sympathy with the movement and believes that an immense amount of good might be accomplished in the manner outlined.

It will be remembered, however, that the resolution having for its object the formation of the Women's Committee was introduced on the afternoon of the last day of the session and owing to a lack of time was passed unanimously by those present without due consideration.

The accidentally faulty wording of the resolution therefore escaped detection and while the mover thereof undoubtedly believed that the resolution, as was intended, actually created a women's Committee of the House of Delegates or of the A. M. A., as a matter of fact it failed to do either and the Committee therefore became a self-appointed one.

The Board of Trustees had no official knowledge of the matter until called upon some time later to meet certain expenses already incurred by the self-appointed Committee. The board believes this a matter of considerable importance.

Should the centralized Bureau above mentioned be created by the House of Delegates at this time, then this Committee would be properly taken care of as a part of the Bureau, otherwise some action should be taken giving this Committee proper standing and defining its duties.

We are pleased to say that the new building authorized by you at your last meeting is in process of erection. Considerable delay was experienced in securing satisfactory bids for the work on account of industrial conditions, but the contracts call for the completion of the building by October 1 and unless some unforeseen complication arises it seems likely that the terms of the contract will be fulfilled.

Appended hereto will be found a detailed report of the business side of the Asssociation and of The Journal, together with an elaborate report from the auditors, bringing everything along these lines down to the end of the fiscal year.

In conclusion the Board may be permitted to express its belief that the future of the Association never was so bright as at the present time.

The profession through the land, year by year is becoming more firmly united in bonds of fraternal harmony and every feeling of internal strife is yielding to the universal desire to uplift the profession and to cause such a dissemination of the knowledge of scientific medicine as shall bring to all mankind that greatest of blessings, good health. But in the earnest endeavor to bring to a fruitful issue the ends toward which we strive, let us guard most carefully against the tendency which so frequently and so insidiously creeps into an organization of the strength of this to dip into politics and thus pollute the honorable traditions of our profession.

Remember that our strength lies in a righteous cause honestly fought.

Respectfully submitted, W. T. Sarles,
W. W. Grant, C. A. Dougherty,
Phillip Marvel, W. T. Councilman.
C. E. Cantrell, Wisner R. Townsend, Secretary.
Phillip Mills Jones, M. L. Harris, Chairman.

Addenda to Trustee's Report

SUBSCRIPTION DEPARTMENT

The regular weekly issue of The Journal of the American Medical Association from Jan. 2, 1909, to Dec. 25, 1909 inclusive, 52 issues, was as follows:

January 2	53,891		July 3	55,440	
January 9	53,253		July 10	55,379	
January 16	53,319		July 17	55,145	
January 23	53,338		July 24	55,028	
January 30	53,283		July 31	54,872	
		267,084			275,864
February 1	53,476		August 7	55,333	
February 13	53,381		August 14	56,469	
February 20	53,457		August 21	54,600	
February 27	53,452		August 28	54,602	
		213,766			221,004
March 6	57,052		September 4	54,594	
March 13	55,644		September 11	54,519	
March 20	56,339		September 18	54,213	
March 27	56,409		September 25	54,140	
		225,444			217,466
April 3	55,923		October 2	54,050	
April 10	56,040		October 9	54,408	
April 17	56,368		October 16	56,044	
April 24	56,414		October 23	56,128	
		224,745	October 30	56,707	
May 1	59,106				277,337
May 8	56,528		November 6	54,746	
May 15	54,730		November 13	57,034	
May 22	55,591		November 20	54,957	
May 29	54,814		November 27	57,250	
		280,769			223,987
June 5	56,186		December 4	57,190	
June 12	56,048		December 11	57,123	
June 19	55,120		December 18	57,334	
June 26	55,108		December 25	57,224	
		222,462			228,871

Total issue for twelve months..........2,878,799
Weekly average..........55,361

As will be noticed, the total number of copies issued during 1909 was 2,878,799. The total issue for 1908 was 2,806,900, an increase of 71,899 copies in 1909 over 1908, or a weekly average increase of 1,382 copies.

PERCENTAGE OF PHYSICIANS RECEIVING THE JOURNAL

This table gives the number of physicians (based on the second edition of the American Medical Directory) in the United States, number receiving The Journal and the approximate percentage in each state. Copies to physicians in the United States Army, United States Navy, Marine-Hospital Service, etc., omitted:

State.	Physicians in State.	Number Receiving Journal.	Approximate Per Cent.
Alabama	2,287	648	28.3
Arizona	246	142	57.7
Arkansas	2,553	595	23.4
California	4,313	1,871	43.3
Colorado	1,690	798	47.2
Connecticut	1,424	675	47.4
Delaware	220	78	35.4
District of Columbia	1,231	564	45.8
Florida	786	318	40.4
Georgia	2,887	762	26.3
Idaho	343	161	46.9
Illinois	9,744	5,023	51.5
Indiana	5,306	1,779	33.5
Iowa	3,624	1,854	51.1
Kansas	2,650	1,119	42.2
Kentucky	3,708	1,184	31.9
Louisiana	1,798	735	40.8
Maine	1,198	407	33.9
Maryland	2,012	1,006	50.0
Massachusetts	5,577	2,365	42.4
Michigan	4,109	1,806	43.9
Minnesota	2,204	1,288	62.9
Mississippi	2,054	515	25.0
Missouri	6,332	2,047	32.3
Montana	417	219	52.5
Nebraska	1,776	738	41.5
Nevada	177	75	42.3

North Carolina	1,761	586	33.2
North Dakota	552	341	61.7
Ohio	7,838	2,807	35.8
Oklahoma	2,703	672	24.8
Oregon	782	349	44.6
Pennsylvania	11,056	4,686	42.3
Rhode Island	720	317	44.0
South Carolina	1,141	415	36.3
South Dakota	607	328	54.0
Tennessee	3.303	779	23.5
Texas	5,789	1,527	26.3
Utah	359	213	59.3
Vermont	663	211	31.8
Virginia	2,215	843	38.0
Washington	1,404	700	49.8
West Virginia	1,608	568	35.3
Wisconsin	2,518	1,360	54.0
Wyoming	202	86	42.5

The following table shows the number of members and of subscribers for each year for the past ten years:

	Members.	Subscribers.
January 1, 1900	8,445	4,633
January 1, 1901	9,841	8,339
January 1, 1902	11,107	10,795
January 1, 1903	12,553	12,378
January 1, 1904	13,899	14,674
January 1, 1905	17,570	15,698
January 1, 1906	20,826	17,669
January 1, 1907	26,255	20,166
January 1, 1908	29,382	20,880
January 1, 1909	31,999	18,983
January 1, 1910	33,032	19,832

The above table shows that there was an increase of 1,033 in the membership list taking The Journal, and an increase of 849 in the subscriber's list, or a total net increase of 1,882.

The above do not include *ex-officio* members, exchanges, complimentary copies to libraries, agents, etc.

During the year 1909, 2,706 subscribers were transferred to the membership list.

The actual increase in our mailing list during 1909 was 1,970. During this period, however, there were added to the list 11,504 names. The difference—9,534—represents the discontinuation by death, by ineligibility to membership, by resignation, by non-payment of dues and subscriptions; also a large number were temporarily dropped and restored.

The deaths alone amount to quite a large number. We are not able to give the exact figure. A goodly portion of the members of the Association are elderly men, and the grim reaper each year makes no small inroad on the mailing list. The ratio of deaths among physicians last year was a little over 16 per thousand. The proportion would certainly be this large among our members.

Treasurer's Report

REPORT OF THE TREASURER OF THE AMERICAN MEDICAL ASSOCIATION FOR THE YEAR ENDING DEC. 31, 1909

RECEIPTS

1909.	
Jan. 1—Cash balance in First National Bank........	$ 3,880.46

Respectfully submitted,

FRANK BILLINGS, *Treasurer.*

Auditor's Report

MARWICK, MITCHELL & CO., CHARTERED ACCOUNTANTS

CHICAGO, Feb. 2, 1910.

To the Board of Trustees of the
American Medical Association, Chicago, Ill.

Dear Sirs:

In accordance with your instructions, we have audited the accounts of your Association for the year ended December 31, 1909. We now submit our report thereon, together with the statements detailed in the index appended hereto.

Our examination was conducted along the lines of previous audits and included an inspection of the bonds, which are detailed in Schedule "6," and the certificates of deposit. The cash on hand and in bank was verified by actual count and certification respectively. The vouchers for disbursements were all in order and properly authorized by responsible officers. We made test checks on the voluminous sources of the Association's revenue.

The balance sheet, recorded in Exhibit "A," is in accordance with the books of the Association and presents, in our opinion, a full and fair statement of its financial position on December 31, 1909, as revealed by the books subject, however, to the consideration of the omission of the accrued liability in respect of taxes, and of that in respect of subscriptions and memberships paid in advance. This latter liability is offset in a measure by subscriptions and memberships earned but outstanding, of which no account is taken in the balance sheet. There has also to be considered the probable loss on doubtful accounts receivable.

The following comparative, summarized statement of the assets and liabilities of the Association, as at December 31, 1909 and 1908, is of interest:

	——DECEMBER 31——			
	1909	1908	INCREASE	DECREASE
Assets:				
Property and Plant.	$173,081.86	$183,737.15	....	$10,655.29
Investments	154,231.88	119,231.88	$35,000.00	....
Current Assets....	72,148.42	52,844.97	19,303.45	....
Total Assets....	$399,462.16	$355,814.00	$43,648.16	....
Liabilities	2,926.95	1,146.18	....	1,780.77
Surplus Assets .	$396,535.21	$354,667.82	$41,867.39	

The increase in surplus assets, namely, $41,867.39, arises from the net surplus income of *the Association* for the year under review. Details of the income account, bringing out this surplus, are shown in Exhibit "B" and supplementary schedules.

A perusal of the foregoing statement will show the disposition of the year's surplus income. It has been invested principally in $35,000.00 of certificates of deposit.

The work of the office force is conducted in an intelligent and accurate manner.

We take pleasure in recording our appreciation of the courtesies extended to our representatives and shall be pleased to furnish any information desired on the accounts. Yours truly,

MARWICK, MITCHELL & CO., Chartered Accountants.

INDEX TO STATEMENTS

W. E. Anderson, Virginia.

JUDICIAL COUNCIL

William C. Woodward, District of Columbia, Chairman.
L. M. Shaw, Nebraska.
L. A. Hahn, Oklahoma.
C. S. Huffman, West Virginia.
G. K. Angle, New Mexico.

THE PRESIDENT: We will now listen to the reports of Standing Committees.

Report of the Judicial Council

DR. C. E. CANTRELL, Texas: As chairman of the Judicial Council, I wish to say that the Council has no report to make inasmuch as nothing has come before us on account of the perfect working of the law settling all ethical matters in the county medical societies and the state associations.

Report of the Committee on Medical Legislation

DR. CHARLES A. L. REED, Ohio, Chairman, read this report.

To the House of Delegates of the American Medical Association:

Your Committee on Medical Legislation submits herewith its annual report and as a part thereof submits copies of the American Medical Association Bulletin for March 15 and May 15, 1910, containing the record of the Joint Conference on a Model Medical Practice Act and the Annual Session of the Legislative Conference held at Chicago, March 1 and 2, 1910.

NATIONAL LEGISLATION

The energies of your committee have been largely devoted to the promotion of national legislation calculated to protect the health interests of the people. The first bill relating to this subject was presented to the Senate Feb. 1, 1910, by Hon. Robt. L. Owen, Senator for Oklahoma, and was entitled "A Bill Establishing a Department of Public Health and for Other Purposes." It stands on the calendar as S. 6049. The same bill was introduced in the House by Mr. Creager, April 15, 1910, and is on the calendar as H. R. 24549. It provides, as the title implies, for the establishment of a Department with a Secretary of Public Health in the Cabinet and for the transfer of existing public health agencies to such department. These provisions, irrespective of details, comprise the principle involved in the bill, a principle so distinctly in consonance with the traditional attitude of the American Medical Association that your representatives, in conference with others interested in the subject, early in March, did not feel at liberty to consider any alternative measure.

As a matter of fact no alternative measure had at that time been presented to the Congress, although since then, on April 22, 1910, Mr. Simmons introduced a bill (H. R. 24827) "Establishing a Department of Public Health and for Other Purposes," the essential difference between it and the Owen bill being that it does not provide for representation in the Cabinet, but places the proposed Department in charge of a "Commissioner of Public Health." Another measure has been introduced by Mr. Mann, which provides for dropping the words "and Marine Hospital" from the "Public Health and Marine-Hospital Service" but without otherwise modifying the status of the bureau under that name now occupying a subordinate relation in the Treasury Department. Another bill has been introduced to create a "National Bureau of Health."

The Owen bill has been and is under consideration by the Senate Commitee on Public Health and National Quarantine and several hearings have been had on the subject. These hearings have been largely attended by representatives of distinctly lay interests as well as your Committee, all of whom have urged the passage of a measure embodying the principle of the Owen bill. The details of the measure, as desired and expected by its author, are to be elaborated in Committee. In the meantime, the general proposition based on all the bills now before Congress, has been under consideration by the Committee on Interstate and Foreign Commerce of the House.

Whether any bill will be reported out of either Committee at the present session of Congress cannot be determined at the date that this report is written. Your Committee, however, lays before you with satisfaction the fact that the whole proposition is now pending in Congress; that advanced national legislation along public health lines has been urged by President Taft in his measure to Congress; that he stands ready at the proper time to give the movement further support by a special message; that the people are aroused to the importance of the subject as never before in the history of the country; and, finally, that the character of the opposition is such as to impress the people that they must support this movement for their own protection against dangerous and remediable conditions as well as against the rapacity of ignorant, selfish and venal interests.

LEGISLATION IN THE STATES

During the past winter the legislature has been in session in the following states—Georgia, Kentucky, Virginia, Maryland, Massachusetts, Mississippi, New Jersey, New York, Ohio, Rhode Island, South Carolina and Louisiana. It is impossible to enumerate all of the bills introduced into the legislatures of the various states but a few of them deserve comment.

MASSACHUSETTS

As is the custom in this state a large number of bills of interest to the medical profession have been introduced to the legislature this year calling for much time and labor in their defense or in opposition. With one exception the results of our labors have been fairly satisfactory. The exception alluded to was the bill giving the courts the common law power, already in force in the Federal courts and in those of some of the states, to charge juries upon the expert medical evidence. The bill was reported favorably by the Joint Judiciary Committee, but was rejected in the House.

Among the numerous bills presented, the following were enacted: The creation of a detention hospital for the temporary reception of persons with mental disturbances, who were formerly sent to police stations, etc.; a state board of registration for nurses. Requiring the use of a prophylactic for ophthalmia neonatorum. Regulating the sale of morphin, cocain, etc. Restriction of the use of public drinking cups. Providing for medical inspection of working children. A commission to investigate the increase or otherwise of criminals, mental defectives, epileptics, etc. A bill permitting cities and towns to maintain sanatoria for the care of tuberculosis patients. (The state now has four large hospitals for the care of these people in all stages of the disease.) A bill establishing small school traveling exhibits of tuberculosis.

The following bills failed of enactment: Optometry, 162 to 58. Anti-vaccination. Privileged communications between physician and patient. Healing by unregistered physicians. Bill requiring "Eddyites," hypnotists, etc., to be registered as physicians are. A bill prohibiting the reappointment of members of the state board of registration in medicine. Bill requiring a diploma before taking examination for license to practice medicine. A bill requiring medical instruction in the public schools was given leave to withdraw. The bill making the state Food and Drug law conform to the Federal law was rejected, as in the opinion of the state board of health, it would lower the standard of our state law. A bill allowing appeals from decisions of boards of health and one placing medical schools under the supervision of the Board of Education were rejected.

KENTUCKY

The following bills became laws: an abortion-bill, making the woman a competent witness against the physician or the person inducing the abortion and relieving her of responsibility in case she testified; a vital statistic bill providing for the registration of births and deaths; an appropriation bill providing $30,000 for the state board of health and $10,000 for a hospital for incurables. The optometry bill and the bill appropriating $150,000 for a medical department of the state university, were defeated.

MARYLAND

A pure food bill and midwifery bill, a lunacy law and sanitary bill were passed by the legislature and signed by the governor. The optometry bill passed both houses but was vetoed by the governor. A bill providing for Pasteur treatment of all persons exposed to hydrophobia passed the legislature but was vetoed. A bill reorganizing the board of health became a law. Anti-vaccination and expert testimony bills failed to pass.

NEW JERSEY

In New Jersey, a new medical practice act, known as the Ramsey bill, providing for a board composed of five regulars, three homeopaths, one eclectic and one osteopath, passed both houses but was vetoed by Governor Fort. An anti-vivisection bill failed to become a law.

NEW YORK

The principal fight in New York was centered around the anti-vivisection bill, a determined effort to pass which was made by the advocates of state restriction of animal experimentation. So far the bill has failed of passage.

OHIO

A large number of bills of interest to the medical profession were introduced of which the following were passed: bill creating the office of state inspector of plumbing; bill restricting the sale of cocain; a criminal abortion bill granting immunity to women and accepting dying declarations; a bill providing for elementary schools for tubercular children. The following bills were introduced but failed to pass: bill authorizing the state board of health to establish a bureau of infectious diseases; bill providing for medical inspection of school children; bill regulating itinerant vending of medicines and nostrums; a medical advertising bill; a Christian Science bill; a bill providing for the sterilization of criminal and defective classes. The legislature passed a bill creating a state board of optometry but it was promptly vetoed by the Governor in one of the strongest presentations of the subject that has yet appeared.

MISSISSIPPI

The following measures, endorsed by the state medical association were introduced into the state legislature: amendment to the medical practice act; a vital statistics bill; midwifery bill and a bill restricting the sale of cocain.

WASHINGTON

A new medical practice act was adopted in this state. An expert testimony bill failed to pass.

VIRGINIA

A bill providing a state board of examiners for chiropractice failed to pass.

LOUISIANA

The Louisiana legislature did not convene until May. The only measure reported so far is a bill for the collection of vital statistics which, it is hoped, will become a law.

BUREAU OF MEDICAL LEGISLATION

The work of the Bureau of Medical Legislation has been continued as outlined in last year's report. There is a decided and gratifying increase in the use being made of this bureau by state boards of health, medical examining boards, officers of state societies and members of the profession in general. In accordance with the instructions of the Committee, the secretary has secured copies of public health laws of the various states. These were collected with a view to the publication of a handbook on medical legislation. Complete copies of all laws have been received from all of the states except Arkansas, Oregon, South Dakota, Idaho, New Mexico and South Carolina. The two latter states are at present preparing the material for the bureau but it has not yet been received. There are at present on file in the bureau over 300 complete laws, referring to various public health matters and covering 43 states. It was found that the publication of the text of the laws complete would involve the preparation of a volume of over 2,000 pages and that the demand for such a book was too limited to justify the expense involved, furthermore, the present crowded condition of the mechanical department of the American Medical Association has made it impossible up to the present to issue such a volume. When the Association has completed its new building it may be possible to issue a volume containing abstracts of these public health laws.

The collection and classification of supreme court decisions regarding medical practice acts has been practically completed. We now have on hand about 200 supreme court decisions, classified and indexed, as well as reference to court reports. But little additional matter is needed to prepare this matter for publication and it will probably be issued in book form as soon as possible. The same work is also being carried on regarding decisions of supreme courts interpreting public health laws.

COMMITTEE FOR THE RELIEF OF MAJOR CARROLL'S WIDOW

At the Washington Conference in 1909, a committee composed of one member from each of the three government services, one member from the District of Columbia and one member at large was appointed to raise by subscription the money necessary to pay off the mortgage on the home purchased by Major James Carroll for his family just previous to his death. This committee consisted of Major M. W. Ireland, chairman, U. S. A., Surgeon W. H. Bell, U. S. N., Surgeon John F. Anderson, U. S. P. H. & M.-H. S., Dr. John D. Thomas, District of Columbia, and Dr. A. S. von Mansfelde of Nebraska. It rendered a partial report at the Atlantic City Session in 1909. At the Chicago Conference on March 2, the committee reported that the entire indebtedness against the property had been wiped out and that the committee now held the property in trust for Mrs. Carroll and that it had in its possession $627.57 over and above all requirements which it was ordered to expend for the benefit of Mrs. Carroll and her family. The total amount raised by the committee, as shown by its final report, was $8,431.55. The committee wishes to call attention to the admirable and expeditious manner in which this money was raised as well as the generous response to requests for contributions. Members of the Association will remember the long delays and difficulties involved in collecting subscriptions for the various memorials which the Association has from time to time undertaken to establish. Most of them have required years of effort. The committee for the relief of Major Carroll's widow not only was able to subscribe and collect the entire amount needed in a very few weeks but actually collected more than was needed and finally found it necessary to publish several requests to the profession to cease sending in contributions.

CONFERENCE ON A MODEL MEDICAL PRACTICE ACT

In accordance with the instructions of the House of Delegates, issued to the Committee at the Atlantic City Session in 1909, a joint conference with the Council on Medical Education was arranged for February 28 to March 2, 1910, in Chicago. The full proceedings of the Conference appear in the *American Medical Association Bulletin* for January, March and May, the January number being held until after the conference in order to include the proceedings. The three days' session was largely attended, as shown by the registration of 167. The proceedings constitute probably the most exhaustive and careful consideration of the question of medical practice ever secured. The discussion held Tuesday morning and evening and the four papers presented at the afternoon session on Tuesday, cover practically every phase of the question. The proceedings show clearly that we have by no means as yet secured unanimity among our own members as to the fundamental principles underlying the regulation of the practice of medicine and that much study and careful discussion will be necessary before uniformity can be secured, even on essential points. By instructions of the conference the work of formulating a model act was assigned to a committee appointed by the chair and consisting of Dr. C. S. Bacon, chairman, Chicago, Dr. S. D. Van Meter, Colorado, Dr. W. H. Sawyer, Michigan, Dr. F. J. Lutz, Missouri, and Dr. A.

R. Craig, Pennsylvania. To this committee was referred all the material on this subject in order that they might draft a bill for submission and further consideration. Dr. S. D. Van Meter of Colorado has submitted a bill as a basis for discussion and criticism, which has not yet been acted on by the committee. We submit it herewith for the consideration and criticism of the House of Delegates.

A BILL FOR AN ACT TO PROTECT THE PUBLIC HEALTH AND REGULATE THE PRACTICE OF MEDICINE

Be it enacted, etc.

Section 1. A board is hereby established to be known by the name and style of the State Board of Medical Examiners. Said board shall be composed of nine practicing physicians of integrity and ability, who shall be residents of, and have been duly licensed to practice medicine in this State, and who shall have been graduated from medical schools of high educational requirements and standing, and who shall have been engaged in the active practice of their profession within this State for a period of at least five years. Said board shall perform such duties, and possess and exercise such powers, relative to the protection of the public health and the control and regulation of the practice of medicine in this State as shall by law be prescribed.

Sec. 2. The Governor shall appoint nine physicians, who shall possess the qualification specified in Section 1 of this act, to constitute the members of said board. Said members shall be so classified by the Governor that the term of office of three shall expire in two, three in four and three in six years from the date of appointment. Biennially thereafter the Governor shall appoint three members, who shall posess the qualifications as specified in section 1 of this act, each to serve for the term of six years; and he shall fill vacancies in the membership of said board for unexpired terms as soon as practicable. Said board shall biennially elect a president, a vice-president and a secretary-treasurer from their membership, and shall adopt a seal, which they shall affix to all licenses issued by them. They shall, from time to time, adopt such rules and regulations as they may deem necessary for the performance of their duties, and a schedule of minimum educational requirements, which shall be without prejudice, partiality or discrimination as to schools of systems of practice of medicine. When an applicant for a license offers to the board satisfactory proof that he has complied with such educational requirements as are specified in said schedule, the board shall accept such proof as sufficient evidence of the educational qualifications of the applicant to entitle him to a license without examination. Said board shall meet in the city of ...., on the first Tuesday of January, April, July and October of each calendar year, and at such other times and places as may be designated by them as necessary for the performance of their duties.

Sec. 3. Said board shall have authority to administer oaths, to summon witnesses and to take testimony in all matters relating to their duties. When the board in the transaction of any of their business, or in the conduct of any hearing, or when any person interested in any such business or hearing, shall desire to secure the presence or testimony of any person before said board, said board, or such person, may procure subpoenas from the clerk of the .... Court of the county wherein such business or hearing is to be transacted or conducted before said board, and the clerk of such court is hereby directed to issue such subpoenas, in the name of the people of the State, commanding the persons whose names shall be given to such clerk by said board, or by such person so interested in such business or hearing, to appear before said board at a certain time and place fixed by said board for the transaction of such business or conduct of such hearing and then and there to testify in the matter of such business or in such hearing. If any person so commanded to appear and testify shall fail or refuse to obey such subpoena, he shall be dealt with by said .... Court in the same manner and to the same effect as though such subpoena had commanded such person to appear and testify in a cause on trial in said court. Fees, or other charges or payments, which may be demanded by any person so commanded to appear and testify shall be only those which may be demanded by witnesses in causes in the .... Court and only under the same circumstances. Such subpoenas shall be served in the same manner as are subpoenas for trials in the .... Court, and they shall be in substantially the same form. Said board shall issue licenses to practice medicine to all persons who shall furnish satisfactory evidence of qualifications to do so under the provisions of this act and the rules and regulations of the board. Such licenses shall be signed by the president and attested by the secretary-treasurer of the board under their seal. It shall be the duty of the secretary-treasurer under the direction of the board personally or by a deputy duly authorized thereunto by said board to aid the several district attorneys of the State in the enforcement of this act and in the prosecution of all persons who have violated any of its provisions.

Sec. 4. No person shall practice medicine in this State unless he shall have made application to said State Board of Medical Examiners, through the secretary-treasurer thereof, upon such form and in such manner as shall be adopted and prescribed by said board, for a license so to do, and shall have obtained from said board and shall possess in full force and virtue a valid license so to do; and any person who shall practice medicine in this State without having made such application and having received and without still possessing such a license shall be deemed to have thereby violated the provisions of this act. All applicants for a license to practice medicine or for a restoration of any such license which have been revoked shall furnish the board with satisfactory evidence of good moral character.

Sec. 5. The manner of determining the qualifications of any person to practice medicine shall be such as shall be adopted by the State Board of Medical Examiners. Examinations of applicants for licenses to practice medicine shall be made by said board according to the methods deemed by them to be the most practicable and expeditious to test an applicant's qualifications. Each applicant shall be designated by a number instead of his name, so that his identity shall not be disclosed to the members of the board, until the examinations shall be graded. The subjects of written, oral or clinical examinations for applicants shall be as follows: Anatomy, physiology, chemistry, symptomatology, toxicology, pathology, surgery and obstetrics; but there shall be no examination on materia medica and therapeutics. An applicant's credentials relating to his general reputation, his preliminary education and the courses of study he has pursued; the degrees he has received; the number of years he has been engaged in the lawful practice of medicine; his experience in hospitals, medical departments of the army, navy and public health and marine-hospital service; licenses granted to him by other states and countries; and his experience as a teacher of medicine, shall be given due consideration by the board in determining his qualifications to practice medicine. When convinced by an investigation of an applicant's credentials that he is qualified to practice medicine the board may grant him a licence thereon without examination.

Sec. 6. Every person who shall receive a license from the State Board of Medical Examiners shall have it recorded immediately in the office of the recorder of deeds of the county in which he shall maintain an office for the practice of medicine, and shall likewise have it recorded in any county in which he shall practice medicine regularly. The recorder of deeds of each county in this State shall keep for public inspection, in a book provided for that purpose, a complete list and description of the licenses recorded by him. When any such license shall be presented to him for record he shall stamp or write upon the back thereof his signed memorandum of the date when such license was presented for record. If the name of any person shall not so appear in such book in any particular county in this State in connection with a description of such license provided for in this act, such fact shall be prima facie evidence in any civil or criminal action involving the practice of medicine by such person in such county that such person does not possess in full force or virtue a license to practice medicine in this State.

Sec. 7. The term practice medicine, as used in this act, is hereby defined to mean holding one's self out to the public as being engaged within this State in the diagnosis or treatment of diseases or injuries of human beings; or the suggestion, recommendation or prescribing of any form of treatment for the intended palliation, relief or cure of any physical or mental ailment of any person, with the intention of receiving therefor, either directly or indirectly, any fee, gift or compensation whatsoever; or the maintenance of an office for the examination or treatment of persons afflicted with disease or injury of body or mind; or attaching the title of M.D., surgeon, doctor, or any word or abbreviation to his name, indicative that he is engaged in the treatment or diagnosis of the diseases or injuries of human beings. If any person shall hold himself out to the public as being engaged within this State in the diagnosis or treatment of diseases or injuries of human beings; or shall suggest, recommend or prescribe any form of treatment for the intended palliation, relief or cure of any physical or mental ailment of any person with the intention of receiving therefor, either directly or indirectly, any fee, gift or compensation whatsoever; or shall maintain an office for the examination or treatment of persons afflicted with disease or injury of body or mind; or shall attach the title of M.D., surgeon, doctor or any word or abbreviation to his name indicative that he is engaged in this state in the treatment or diagnosis of diseases or injuries of human beings, and shall not then possess, in full force and virtue, a valid license to practice medicine without complying with the provisions of this act and in violation hereof. Nothing in this act shall be construed to prohibit gratuitous service in case of emergency, nor a lawfully practicing physician of another state or territory from attending a particular case in this state.

"[nor the practice of religious tenets or religious rites or ceremonies as a form of religious worship or devotion without charge or compensation for the administration thereof."

The foregoing has no just place in a Model Medical Act, but is recommended as the best manner of meeting church opposition. When it becomes necessary insert this clause in Section 7.

"Nor to prohibit commissioned surgeons of the United States Army, Navy or Public Health and Marine-Hospital Service from performing their lawful duties in this state as such."

The foregoing is unnecessary, but it does no harm.

"Nor to prohibit any person from engaging in the administration of massage or similar manual treatment, when not representing himself as a doctor, physician or surgeon."

The foregoing has no just place in a Model Medical Act, but is recommended as the best manner of meeting opposition from the so-called "non-drug" doctors, such as osteopaths, chiropractics, neuropaths, etc. When it becomes necessary insert this clause in Section 7.]

Sec. 8. The State Board of Medical Examiners may refuse to grant, or may revoke, a license to practice medicine in this state, and may cause a licentiate's name to be removed from the record in the office of any recorder of deeds, upon any of the following grounds, to-wit: The employment of fraud or deception in applying for or securing a license, or in passing the examination provided for in this act; the practice of medicine under a false or assumed name, or in personation of another physician of this state or of any state, territory or foreign country, of a like or different name; the conviction of a felony or of a [illegible] al turpitude; habitual intemperance in the us [illegible] otics or stimulants to such an extent as to [illegible] fessional duties; the procuring [illegible] attempting to procure a crimi [illegible] malpractice resulting in the permanent injury or the death of the patient; the obtaining of a fee, either directly or indirectly, either in money or in the form of anything of value, or in the form of a financial profit, either as personal compensation, or as compensation, charge, profit or gain for an employer, or any other person or persons, on the representation that a manifestly incurable, sick, diseased or injured condition of any person can be permanently cured; causing the publication, circulation, exhibition or display publicly of an advertisement, notice or information of any medicine or means whereby the monthly periods of women can be regulated, or the menses, if suppressed, can be reestablished, or whereby an abortion can be accomplished; causing the publication, circulation, exhibition or display publicly of any advertisement relative to any disease of the sexual organs, or relative to the treatment, alleviation, palliation, cure or prevention of any disease, weakness or condition of the sexual organs.

Sec. 9. Said board in determining whether any applicant for a license to practice medicine is morally, educationally and otherwise qualified to receive such a license shall upon their own initiative make diligent inquiry and investigation whether such an applicant has at any time done any of the acts constituting any of the foregoing grounds; and they may refuse to grant a license to practice medicine to any person whom after such inquiry and investigation they shall find guilty beyond a reasonable doubt of having done any of such acts. But said board shall not refuse to grant such a license under such circumstances before such applicant has had reasonable opportunity, and at least thirty days' notice, to appear before the board in person and by counsel and present in his behalf such statements, testimony, evidence and argument as he may desire to call to the attention of the board. For the purpose of considering the revocation of any license to practice medicine said board shall have the power upon their own initiative to take notice of the commission by any person holding such a license of any of the acts constituting any of the foregoing grounds, and may make an investigation to determine the probability of the commission of any such act by any such person, and, if they find such probability great, they shall notify such person of such finding, and they shall fix and give thirty days' notice to him of the time and place and the particular grounds when, where and upon which they will conduct a hearing for the presentation of evidence as to whether he has committed any of said acts constituting any of such grounds. At such hearing such person shall be accorded a reasonable opportunity to present to the board in his defense in person and by counsel, such statements, testimony, evidence and argument as he may desire to call to the attention of the board. Any person may file a complaint before the State Board of Medical Examiners against any person who holds a license to practice medicine under the laws of this state, or who is an applicant for such a license, with a view of having the board revoke or refuse to grant such a license, on any of the foregoing grounds. In case any such complaint is filed against any such person, he shall be given a hearing thereon by the board. A copy of such complaint, together with a notice of at least thirty days of the time and place when said board will conduct a hearing thereon, shall be given each person against whom such complaint has been made and he shall be accorded a reasonable opportunity to present to the board in his defense in person and by counsel, such statements, testimony, evidence and argument as he may desire to call to the attention of the board. The State Board of Medical Examiners may at any time after the refusal or revocation of a license as aforesaid, grant or restore, such a license to the person affected. Any person to whom such a license is so restored shall pay to the secretary-treasurer a fee of ten dollars upon the restoration thereof. The action of the State Board of Medical Examiners in refusing to grant or in revoking a license to practice medicine may be reviewed by the .... Court under the common law writ of certiorari.

Sec. 10. Any person who shall practice medicine in this state without complying with the provisions of this act, or any person who shall violate any of the provisions of this act, shall be deemed guilty of a misdemeanor, and upon conviction thereof, shall be punished by a fine of not less than fifty dollars nor more than three hundred dollars, or by imprisonment in the county jail for not less than ten days nor more than thirty days, or by both, in the discretion of the court. Any person who shall present or attempt to file as his own the diploma or certificate or credentials of another, or who shall give false evidence or present any altered or forged instrument or writing of any kind to the State Board of Medical Examiners, or any member thereof, in connection with an application for a license to practice medicine, or in any hearing before said board, or who shall practice medicine under a false or assumed name, or who shall falsely personate another practitioner of a like or different name, shall be deemed guilty of a felony, and upon conviction thereof shall be punished by imprisonment in the State Penitentiary for a term of not less than one year, nor more than ten years, at hard labor.

Sec. 11. Each applicant for a license to practice medicine shall pay to the secretary-treasurer of the State Board of Medical Examiners a fee of twenty-five dollars, which shall accompany the application.

Sec. 12. All fees received by the State Board of Medical Examiners and all fines collected by any officer of the law under this act, shall be paid to the secretary-treasurer of said board, who shall, at the end of each and every month, deposit the same with the State Treasurer, and the said State Treasurer shall place said money so received in a special fund to be known as the fund of the State Board of Medical Examiners, and shall pay the same out on warrants drawn by the Auditor of the State therefor, upon vouchers issued and signed by the president and secretary-treasurer of said board. Said moneys so received and placed in said fund may be used by the State Board of Medical Examiners in defraying their expenses in carrying out the provisions of this act. The secretary-treasurer of said board shall keep a true and accurate account of all funds received and all vouchers issued by the board; and on the first day of .... of each year he shall file with the governor of the state a report of all receipts and disbursements for said board for the preceding fiscal year. Members of said board shall receive a per diem for the time during which they shall be actually engaged in the discharge of their duties; and the secretary-treasurer shall receive a salary; said per diem and salary shall be fixed by the board, and, together with other expenses, shall be paid out of said fund of the State Board of Medical Examiners.

COOPERATION IN THE CONFERENCE ON UNIFORM STATE LAWS CALLED BY THE NATIONAL CIVIC FEDERATION

Two members of the National Legislative Committee and the
General Secretary of the American Medical Association repre-
sented the American Medical Association in this conference
which was composed of members of the various state commis-
sions of uniform laws, representatives of most of the important
commercial and civic clubs and other organizations of the coun-
try, including the insurance companies and labor organizations.
Dr. Simmons was made secretary of the committee on resolu-
tion, and succeeded in getting incorporated into the resolutions
which were adopted by the conference, one favoring uniform
state laws on Foods and Drugs, one on Uniform Vital Statistics
and one favoring a uniform medical practice act. The Civic
Federation has since undertaken to establish branches in each of the states as state councils on uniformity in laws and it is hoped that through these agencies the efficiency of the work of the state commissions on uniform state laws will be greatly increased. It is also expected that the cooperation of the Civic Federation and its branches and that of the commissions on uniform laws will help greatly in securing the passage of uniform laws on vital statistics, pure foods and drugs, medical practice and other subjects in which the medical profession is vitally interested.

PROSPECTIVE STATE LEGISLATION

During the winter of 1910-11 the legislatures will meet in thirty-six states. The indications are that there will be a flood of objectionable bills introduced, especially osteopathy, optometry, anti-vivisection, anti-vaccination, Christian Science, drugless healer, etc. Only by the most untiring efforts and ceaseless vigilance can the passage of these pernicious measures be prevented. *The Committee and the Bureau therefore ask for the heartiest cooperation of state associations and* legislative committees as well as the support of all members of the organization *in their efforts to prevent the breaking down* of laws for the protection of the public health in the various states.

BUREAU OF PUBLICITY

The Committee has learned from the experience of past years, both in national and state legislative campaigns, that any effort to secure the *adoption of desirable laws for the* protection of the public health, either in state legislatures or in Congress, must, if successful, be *preceded by a campaign of* publicity and public education *in order that the people and* their representatives in legislative assemblies may understand the necessity of such laws. Education not only of the general public but of the medical profession as well is also a necessary part of any campaign for better conditions. For many years the use of newspapers, magazines and other means of influencing public sentiment has been practically monopolized by commercial interests who had personal and in many cases mercenary *reasons for desiring* the support of the public. The medical profession in past years has been far too negligent in this particular. In order to accomplish anything of permanent value we *must have* the support *and cooperation of public* sentiment. This can only be secured through public enlightenment of our aims and motives. Public education must necessarily precede legislation and the only rational plan is for such instruction to be in the hands of the same body as that charged with the oversight of legislative matters. Both for financial reasons and because the committee did not desire to conflict with any other committees or boards of the Association, the organization of a Department of Publicity has been deferred although the necessity for it has been apparent. The Committee, therefore, strongly urges that it be authorized to establish a *press bureau for the* education of public opinion both *on* general health topics and as a precedent measure for any legislative campaign. The time has passed when any fears as to the danger of such a course being regarded as undignified and unprofessional should deter us. If the American public is not informed and enlightened by the reputable medical profession it will be biased and influenced by the quack, the charlatan, the manufacturer of impure and adulterated foods and drugs *and by all the other selfish interests which have* so long preyed on the people.

Respectfully submitted,

Charles A. L. Reed, Chairman,
Charles S. Bacon,
George W. Gay,
Frederick R. Green, Secretary.

DR. REED TENDERS RESIGNATION

To the President and House of Delegates:—I beg leave herewith to present my resignation as a member of the Committee on Medical Legislation, to become effective on the selection of my successor at the present session of the Association.

In taking this step at this time I deem it important to
explain that I tendered my resignation to the President in
October of last year, but that I subsequently withdrew the
same on the representation that it was impracticable to fill the
vacancy, *ad interim*, and I knew that the pressure of duties on
the Committee made it of the highest importance that it should
be in working condition during the legislative and congres-
sional period embraced by the last eight months. Now, how-
ever, that that period has practically passed, or at least will
conclude with the adjournment of the Congress within a few
weeks, and in view of the fact that the House of Delegates now
in session can fill the vacancy thus created, I renew my resig-
nation for the reasons that actuated me in the first instance.

EXPANSION OF LEGISLATIVE ORGANIZATION

I desire that these reasons shall be distinctly understood. In the first place I have been honored with this position for the last eight years, which I look upon as a longer period than should be occupied by any one man in the chairmanship of any one committee in an organization of this representative character. In the next place, in view of the imperative demands of my practice, the tax in point of time, money and energy thus imposed is more than should be expected of any one person for so long a time. And, finally, the responsibilities in behalf of all the people, responsibilities that naturally rest on this Association, responsibilities that it cannot and ought not evade, but responsibilities that must be discharged through your legi [illegible] make it imperative that that legislative [illegible] retaining its present essential features, must be placed upon a different basis. I urge this view in full recognition of the high efficiency that has been displayed by your National Legislative Council and by the National Auxiliary Legislative Committee, the continuance of both of which, in their present forms, I urge as vital to the perpetuity of our influence in determining affairs in this country. The central Legislative Committee ought, however, to be brought into association and correlation with every other committee of whatever character, the object of which is to disseminate knowledge for the safe guidance of the people. This can only be done by a strong cohesive organization in which there must be the largest liberty of individual opinion but in which the wisdom of the majority shall control and from which mere obstructionists must be eliminated with as little ceremony as may be compatible with good manners and established forms.

The whole legislative and educational organization must furthermore be given status as a Council which, in this Association has come to imply the maximum of dignity and force. But even if all these changes were made, this propaganda in behalf of the people must still fall short of a full measure of success unless it is organized on what, for a better designation, must be called business principles. By this I mean that the Bureau of Legislation at Chicago, efficient as it is, must be strengthened and its scope widened. The Chairmanship of the Council of Legislation must command all the time of a capable member who should be adequately paid for his labors. The time has passed when any organization, however altruistic its purposes, can throw the whole burden of its duties on a single person and expect to pay the obligation by the honor thus conferred. Then let every person take his turn and do his duty in a designated place but refrain from participation in sporadic movements for personal conspicuity to be attained by the usurpation of functions already provided for in the more broadly organized propaganda.

COOPERATION IN STATE LEGISLATION

And now that I have said this much I feel that, in justice to the House of Delegates, to my successors, and to myself, I cannot permit my resignation to go forward without mentioning certain other impressions that have been forced on me by my eight years' experience but, which, being personal to myself, may not with propriety be embraced in the formal report of the Committee. These impressions relate to legislative work in, respectively, the states and the Nation. With respect to the states, I may observe that the measures pending before the various legislatures have been kept under the cognizance only through the instrumentality of the Bureau of Legislation. This ought to be kept up and the Bureau ought to be in position, wherever occasion requires, to furnish state legislative committees with literature for their information and guidance. It is, however, to my mind extremely doubtful whether the National organization should ever take a hand in either the promotion or defeat of proposed legislation in any of the states, even when state committees, from a probably mistaken sense of weakness, should request such cooperation.

For any member of the National organization, not a resident of a given state, to appear before the legislature of that state either for or against a given measure, would, under ordinary circumstances, tend to prejudice the cause at issue before the legislators.

UNIFORMITY, LICENSURE AND RECIPROCITY

Model acts or standard forms of legislation for the promotion of the general welfare, but coming under the purview of the police powers of the respective states may, however, be formulated with propriety by a central organization and sent to the different state organizations for presentation to their respective legislatures. In this connection, however, it is to be remembered that the variations in the constitutions of different states necessitate corresponding variations in the statutes enacted in pursuance and by authority of such constitutions. This fact of itself must defeat the absolute uniformity of state legislation along certain lines however much the principles of such legislation may be in unison.

The principle of uniformity in state legislation governing the practice of medicine has been urged with respect to reciprocity in state licensure. At present no two states have identical laws, yet reciprocity in licensure obtains to some extent between a majority of states. From this it would seem that absolute uniformity of statutes is not essential to the object in view. Most states extend reciprocity only to those who have procured license by examination and decline to extend the same privilege to members of the profession, whether graduates or not—whether lowly or honored, humble or distinguished—who obtained license by registration at the time the respective acts went into effect. Every state that maintains this restriction perpetrates not only an injustice but an insult not only to the majority of the reputable physicians within its own borders, but to those within the borders of every other state in the Union. The pretention that the so-called "legal practitioners"—those to whom license was given on years-of-practice qualification—are any less qualified intellectually or morally, in any one state than in another, or that they are any more disposed to migrate to or from one state than to or from some other state, would probably be exploded in the light of the real facts were they once authoritatively ascertained. That there is any essential inequality between the qualifications of the examiners themselves when selected by political methods in the different states is, likewise, probably far from the facts. That these selections are generally, but not always made on a political basis, is a matter of common knowledge. "Who shall examine the examiners?" has therefore come to be something more than a derisive pleasantry. It is indeed probably true that the majority of state examiners selected by these political methods and vested with the duty of judging the work of our ablest universities, could not to-day pass the matriculation examination, let alone the examination for licensure prescribed by themselves and by their respective boards.

The proscriptive clause in many of the state laws, or in the regulations passed in pursuance of such laws, whereby medical teachers are excluded from membership in examining boards, not only deprives these bodies of the ability represented by the leaders of the profession in their respective states, but is an obvious invasion of personal rights that would not stand the test if carried to the courts. But these conditions are so nearly uniform in the respective states that they to-day, under the comity of states and with but slight adjustment of differences, demand the very general adoption of a policy of wide open reciprocity. At any rate these and other matters demand most careful consideration before anything like a standard act is promulgated under the auspices and with the approval of the American Medical Association.

EXISTING STATE MEDICAL LAWS AND THE PROPAGATION OF CULTS

One of the other matters to which I invoke your attention is the fact, as I see it and believe it to exist, that existing state medical laws are directly responsible for the propagation of sectarianism in medicine and that they have failed properly to protect the people against ignorant, unscrupulous, rapacious and otherwise dangerous cults. This conclusion, forced on me by several years' study of legislative, professional and social tendencies, is to-day confirmed by conditions as they actually exist, with only a few honorable exceptions, in every state in the Union. These conditions call for very careful study of cause and effect—too comprehensive to be treated in detail at this time—but I feel that I may take opportunity only to say that these laws, while originally seeking to do away with sectarianism based on half knowledge or no knowledge, did so by legitimatizing the better educated sects in existence at the time the laws were passed. But the sects were recognizd either by separate boards, or in the personnel of so-called mixed boards, the latter arrangement being effected in some instances by agreement with the appointing power. In each instance "systems" or "methods of cure" were recognized in some way in the preliminary registrations or by special questions on therapeutics in the later examinations for licensure.

Now if these sects were recognized why should not other sects be recognized? And if these particular sects may prescribe the knowledge, both general and special, by which they shall become legitimatized, why may not other sects prescribe the knowledge, both general and special, by which they in turn shall be legitimatized? The error was in the beginning when there was, as there is now, practical agreement between these better educated sects on what shall comprise the general fundamental knowledge that ought to be possessed by everybody who professionally assumes the care of disease or injury. But this was at a time when the special knowledge that characterized such other educated sects was more insisted on than it is to-day. In other words each such sect then went just as far as the others would let it in getting its peculiar pills and potions into the statute books. Varnish it as you may, that was the fact then, and it remains a fact to-day.

But a law differs from a statute in that the law is a regulation and only such regulation of society as the people will support. It is important to bear this distinction in mind because, whatever my be the provisions of the statutes, the people never have, never will, and, in my opinion, never ought to give the force of law to any statute that, even inferentially or constructively, seeks to give monopoly of cure to either men, methods, cults or systems. I am convinced that, whatever may be placed in the statutes, the most that the law will ever do will be to prescribe and enforce a common, safe and rational foundation for all persons or plans of cure—all cults, systems or denominations of medicine—that have for their object the professional care and conduct of disease or injury of the human family.

This foundation must consist of a knowledge not only of the fundamental studies for everybody, but of human anatomy, physiology, bacteriology, pathology, diagnosis, hygiene, sanitation, obstetrics and surgery, and such allied branches as may be essential to a comprehension of these complex topics. The always more or less speculative question of remedies and cure in their broadest sense ought to be and must be left to the intelligence of one thus otherwise equipped. All cults standing on such a foundation may be considered safe. The attempt to do more will defeat the object in view as that object is to-day being defeated. The attempt to do less will be to fail to give society the protection to which it is entitled. To defer the adoption of this rational basis for our medical legislation will be to await development and multiplication of ignorant cults and isms until by their strength and establishment the necessary reform will be rendered either difficult of accomplishment or impossible. These, too, are considerations to be taken into account before a model practice act is promulgated in the name of the American Medical Association.

THE GUARDIANSHIP OF VICTORY

A victory is not worth gaining unless its fruits are safeguarded against reprisals. This is as true in the matter of progressive medical legislation as it is in warfare between nations. It is, for example, hardly worth while to work seventeen years for a food and drugs act if its power to protect the people is destroyed by executive interpretation in the short space of seventeen months. It is not worth the time and money to establish a national quarantine if by virtue of its uninfluential status it can be browbeaten into ineffectiveness by rapacious commercial interests at infected ports. It is not worth while to create laboratories for hygienic investigation if we are to permit them to ignore the investigation of unknown causes underlying diseases that threaten to decimate the people. We must stand by every vantage point gained in this great movement for the promotion of the general welfare. This can be done only by still further perfecting our already splendid organization and by still further and persistently disseminating its influence throughout society.

To-day, in the movement for a National Department of Health, the isssue is fairly joined between the enlightened element of society under the leadership of the medical profession on the one hand and the ignorant and credulous element of society under the leadership of sinister cults on the other hand. The side will win whose cause best subserves the welfare of the people and that makes the people understand that fact. By this criterion alone shall the contestants be measured and weighed in the final arbitrament. And let it be remembered that this final arbitrament must come at the hands of the plain people whose interests are always first to be considered and without whose support all movements must stop short of progress. This being true, it devolves on every person conversant with the merits of this great movement for the conservation of public health, and on which is predicted our public wealth, to recognize in this question the paramount political issue of the present and succeeding campaign.

THE IMPORTANCE OF POLITICAL ACTION

An issue becomes an issue when it acquires a vote-determining power and not until then. The sooner this particular question thus becomes an issue to be discussed on the hustings and determined at the polls the better for the American people. I am utterly opposed to those who protest against permitting this question to go into politics. The sooner and further we put it into politics and the harder we drive it home with effective organization and courageous leadership the sooner will the voice of science and humanity become effective in the promotion of the general welfare. In that campaign I hope always to be found at my place in the ranks.

I desire to thank the House of Delegates and the members of the American Medical Association for their prolonged manifestations of favor and confidence.

Very respectfully, Charles A. L. Reed.

Cincinnati, Ohio, May 20, 1910.

Dr. Everett J. McKnight, Connecticut, called attention to the omission from the report of the Committee on Medical Legislation of what had been accomplished in Connecticut, although he had sent a report of this work to the Assistant Secretary.

It was moved and seconded that the report of Dr. McKnight be included as a part of the report of the Committee on Medical Legislation.

The motion was carried.

The report was then referred to the Reference Committee on Legislation and Political Action.

The President: We will now hear the report of the Council on Medical Education, Dr. Arthur D. Bevan, Illinois, Chairman.

Dr. Bevan then read the report, which was referred to the Reference Committee on Medical Education.

Report of the Council on Medical Education

To the Members of the House of Delegates of the American Medical Association:

During the past year the second tour of inspection of the medical colleges of the United States has been completed and much additional data collected. From the fact that the medical colleges of Canada furnish so many medical practitioners to the various states and requests for reliable information regarding them has been lacking, these colleges were included in the second tour of inspection so that now the Council has first hand information regarding all the medical schools of the United States and Canada. Since the completion of the actual inspection work the reports regarding the various colleges have been carefully reviewed and compared department by department with a view of finding the average condition. Incidentally, a mass of other data received from reliable sources was found to corroborate the data obtained by the inspections. From this careful study of the conditions actually existing and with a view of the immediate needs of medical education, the following outline of the "Essentials of an Acceptable Medical College" was prepared. Omitting from consideration a number of the utterly worthless medical colleges this outline represents in the majority of points a line considerably below the average of conditions existing in all the colleges of the United States and Canada. The outline is as follows:

1. Strict enforcement of all standards and requirements, the college itself to be held responsible for any instances where they are not enforced.
2. A requirement for admission of at least a four-year high-school education superimposed on eight years of grammar school work, or the actual equivalent education, this to consist of 14 units as defined by the College Entrance Examining Board and required by the Carnegie Foundation for the Advancement of Teaching.
3. As soon as conditions warrant, the minimum requirement for admission should be enlarged to include at least one year's college work each in physics, chemistry and biology and a reading knowledge of at least one modern language, preferably German or French.
4. A requirement that students be in actual attendance in the college within the first week of each annual session and thereafter.
5. That actual attendance at classes be insisted on except for good cause, such as for sickness, and that no credit be given under any circumstances for less than 80 per cent. of attendance on each course.
6. That advanced standing be granted only to students of other acceptable colleges and that in granting advanced standing there shall be no discrimination against the college's full-course students.
7. Careful and intelligent supervision of the entire school by a dean or other executive officer who holds, and has sufficient authority to carry out, fair ideals of medical education as interpreted by modern demands.
8. A good system of records showing conveniently the credentials, attendance, grades and accounts of the students.
9. A fully graded course covering four years of at least 30 weeks each, exclusive of holidays, and at least 30 hours per

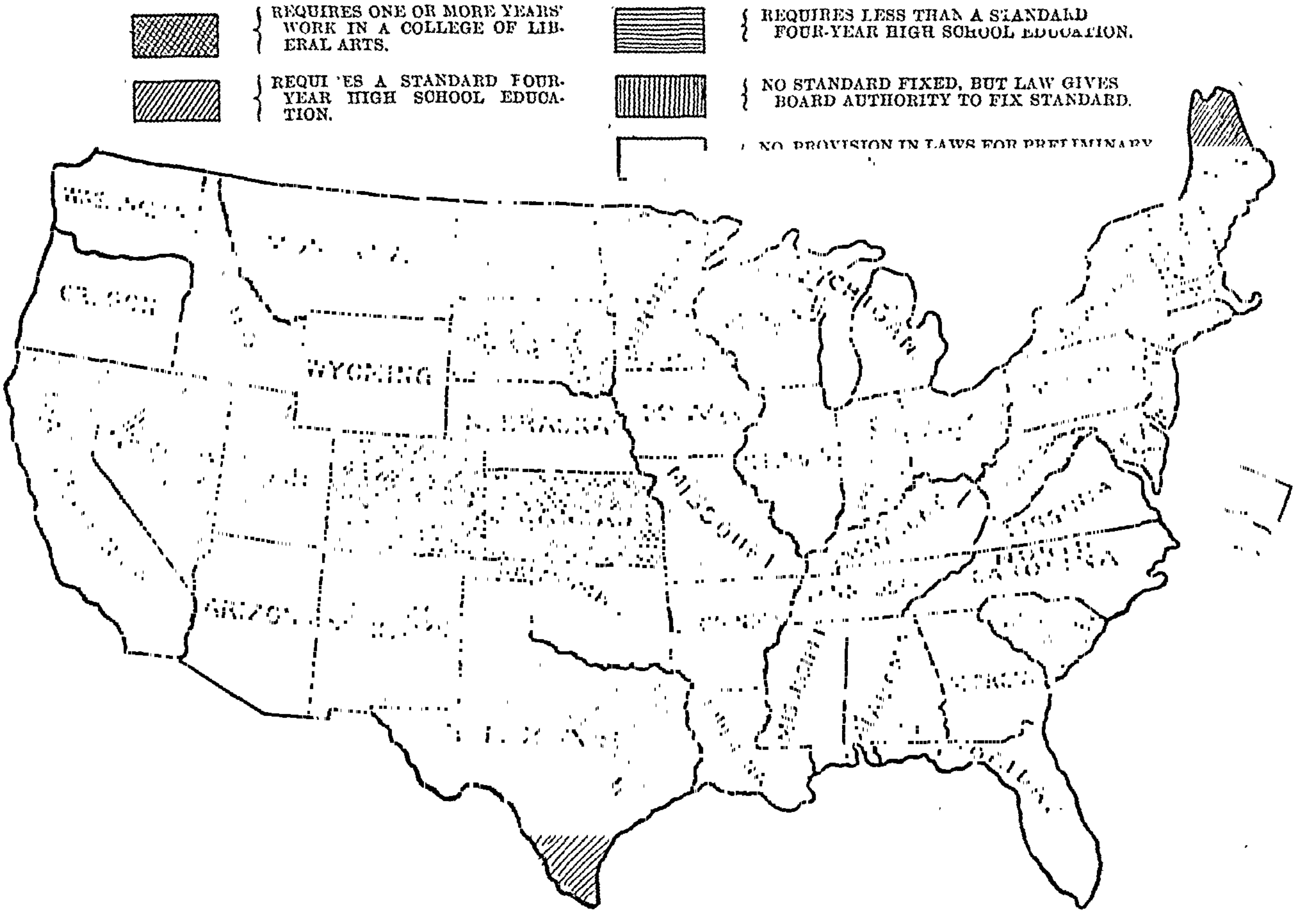
week of actual work; this course should be clearly set forth in a carefully prepared and printed schedule of lectures and classes.

10. Two years of work consisting largely of laboratory work in thoroughly equipped laboratories in anatomy, histology, embryology, physiology, chemistry (inorganic, organic and physiologic), bacteriology, pathology, pharmacology, therapeutics and clinical diagnosis.

11. Two years of clinical work largely in hospitals and dispensaries, with thorough courses in internal medicine (including physical diagnosis, pediatrics, nervous and mental diseases), surgery (including surgical anatomy and operative surgery on the cadaver), obstetrics, gynecology, laryngology, rhinology, ophthalmology, otology, dermatology, hygiene and medical jurisprudence.

12. At least six expert, thoroughly trained instructors in the laboratory branches, salaried so they may devote their entire time to instruction and to that research without which they cannot well keep up with the rapid progress being made in their subjects. These instructors should rank sufficiently high to have some voice in the conduct of the college. There should also be a sufficient number of assistants in each department to look after the less important details.

CHART 1.—STATE BOARD REQUIREMENTS OF PRELIMINARY EDUCATION



REQUIRES ONE OR MORE YEARS' WORK IN A COLLEGE OF LIBERAL ARTS.
REQUIRES A STANDARD FOUR-YEAR HIGH SCHOOL EDUCATION.
REQUIRES LESS THAN A STANDARD FOUR-YEAR HIGH SCHOOL EDUCATION.
NO STANDARD FIXED, BUT LAW GIVES BOARD AUTHORITY TO FIX STANDARD.
NO PROVISION IN LAWS FOR PRELIMINARY
OREGON
WYOMING
NEBRASKA
MISSOURI
ARIZONA
VIRGINIA
CAROLINA

13. The medical teaching should be of at least the same degree of excellence as obtains in our recognized liberal arts colleges and technical schools.

14. The members of the faculty, with a few allowable exceptions, should be graduates of institutions recognized as medical colleges and should have had a training in all departments of medicine. They should be appointed because of their ability as teachers and not because they happen to be on the attending staff of some hospital or for other like reasons.

15. The college should own or entirely control a hospital in order that students may come into close and extended contact with patients under the supervision of the attending staff. The hospital should have a sufficiently large number of patients to permit the student to see and study the common varieties of surgical and medical cases as well as a fair number in each of the so-called specialties.

16. The college should have easily accessible hospital facilities of not less than 200 patients which can be utilized for clinical teaching (for senior classes of 100 students or less), these patients to represent in fair proportion all departments of medicine.

17. The college should have additional hospital facilities for children's diseases, contagious diseases and nervous and mental diseases.

18. Facilities for at least five maternity cases for each senior student, who should have actual charge of these cases under the supervision of the attending physician.

19. Facilities for at least 30 autopsies during each college session (for senior classes of 100 students or less).

20. A dispensary, or out-patient department, under the control of the college, the attendance to be a daily average of 60 cases (for senior classes of 100 students or less), the patients to be carefully classified, good histories and records of the patients to be kept and the material to be well used.

21. The college should have a working medical library to include the more modern text and reference books and 10 or more leading medical periodicals; the library room to be easily accessible to students during all or the greater part of the day; to have suitable tables and chairs and to have an attendant in charge.

22. A working medical museum having its various anatomic, embryologic, pathologic and other specimens carefully prepared, labeled and indexed so that any specimen may be easily found and employed for teaching purposes.

23. A supply of such useful auxiliary apparatus as a stereopticon, a reflectoscope, carefully prepared charts, embryologic or other models, manikins, dummies for use in bandaging, a Roentgen ray or other apparatus now so generally used in medical teaching.

24. The college should show evidences of reasonably modern methods in all departments and evidences that the equipment and facilities are being intelligently used in the training of medical students.

25. A statement in which the college's requirements for admission, tuition, time of attendance on the classes, sessions and graduation are clearly set forth should be given, together with complete lists of its matriculants and latest graduating class in regular annual catalogues or announcements.

DEFINITIONS OF A MEDICAL COLLEGE* AND A MEDICAL SCHOOL†

"An institution to be ranked as a medical college must have at least six (6) professors giving their entire time to medical work, a graded course of four full years of college grade in medicine, and must require for admission not less than the usual four years of academic or high-school preparation, or its equivalent, in addition to the preacademic or grammar school studies."

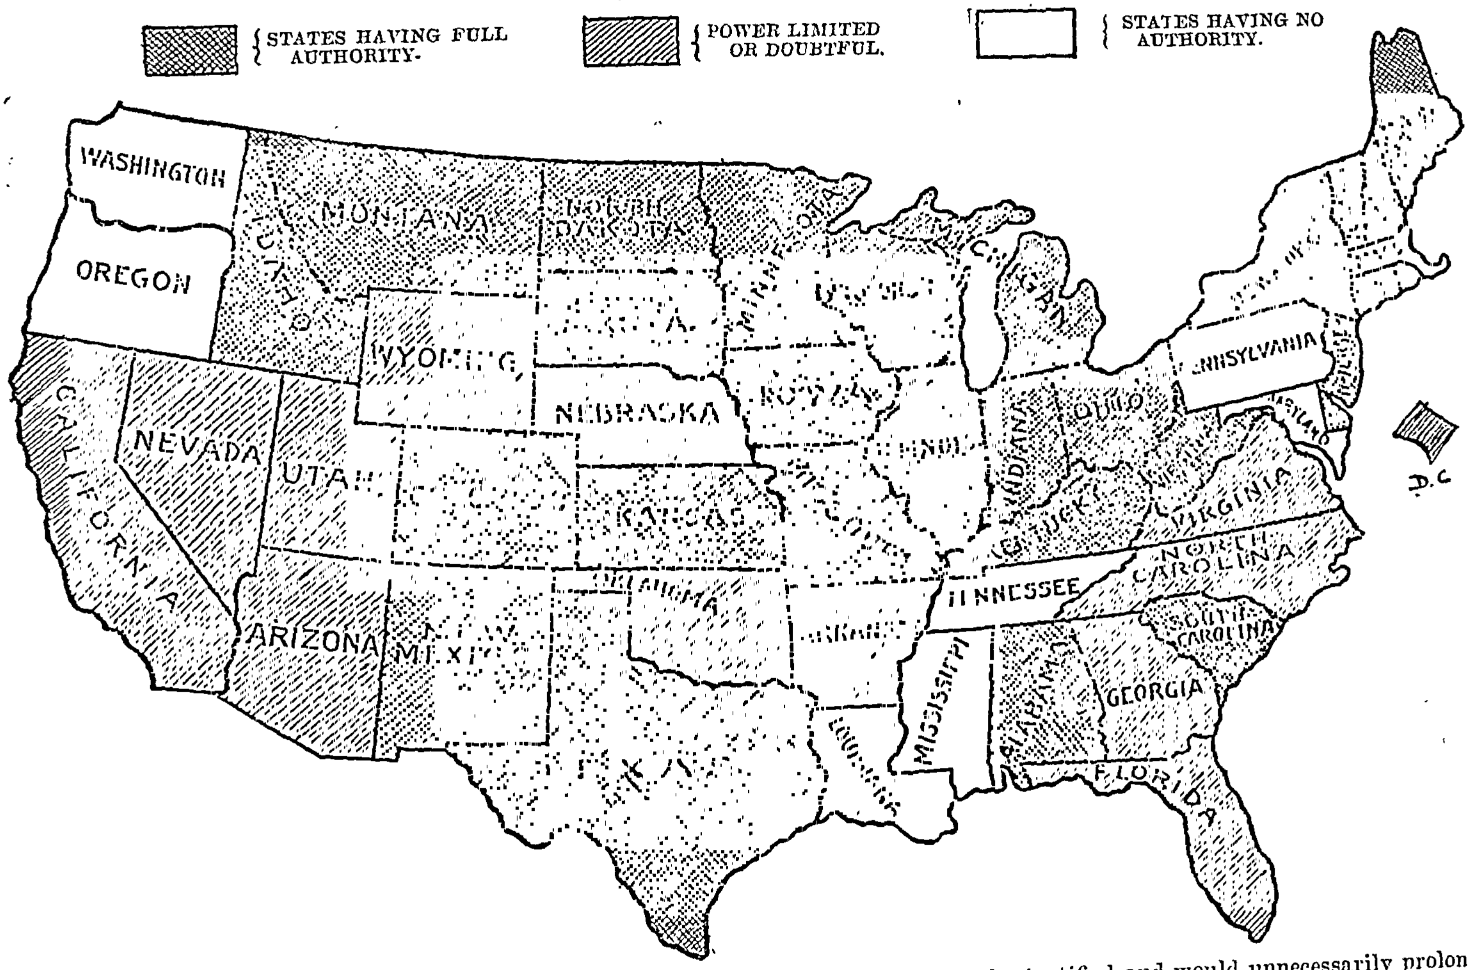
By a medical school as differentiated from a medical college is meant a part of a university requiring for admission the equivalent of two years of collegiate work and which offers instruction of not less than two years' duration, leading to the degree of Doctor of Medicine.

Taking the above outline as a standard, although, as already stated, it represents in most particulars a very low average of the conditions actually existing, the colleges were rated on a civil service basis on the scale of 100. The data relating to each college were grouped under ten general heads in such manner that the groups would have as nearly equal weight as possible, each group allowing a possible 100 points (10 per cent.) and the ten groups aggregating, therefore, a possible 1,000 points (100 per cent.). The ten heads under which the data were arranged are as follows:

1. Showing of graduates before state boards.
2. Requirements and enforcement of satisfactory preliminary education and the granting of advanced standing.
3. Character of curriculum.
4. Medical school buildings.
5. Laboratory facilities and instruction.
6. Dispensary facilities and instruction.
7. Hospital facilities and instruction.
8. Faculty, number of trained teachers, all time instructors, especially of the laboratory branches and extent of research work.
9. Extent to which the school is conducted for properly teaching the science of medicine rather than for the profit of the faculty directly or indirectly.
10. Libraries, museums, charts, etc.

Those colleges receiving a rating of 70 per cent. or above are listed in Class A, those receiving a rating of from 50 to 70 per cent. in Class B, and those rated below 50 per cent. in Class C. Class A colleges may be considered, therefore, as acceptable colleges, those of Class B as colleges which require certain definite improvements to make them acceptable and those of Class C as colleges in which complete reorganization would be required to make them acceptable.

CHART 2.—STATE BOARDS HAVING AUTHORITY TO DETERMINE THE REPUTABILITY OF MEDICAL COLLEGES



Following the first tour of inspection, the Council was criticized in certain quarters for not publishing outright its classification of medical colleges. That classification was not published, however, because the Council desired to give a number of colleges which were contemplating improvements the opportunity to make good. The delay has been more than justified. Many colleges have secured additional facilities, numerous mergers have been brought about and, on the whole, the situation has greatly improved. The general conditions as revealed by the first inspection, however, were given the widest possible publicity so that at the present time any plea of ignorance of the demands of modern medicine is unworthy of consideration and further delay in the presentation of a classified list would not be justified and would unnecessarily prolong the existence of low standards.

With the knowledge that only about half of our medical schools are teaching medicine in an acceptable way and with the power possessed by the majority of the state boards to determine what constitutes a medical school in good standing, it would seem easily possible for the state boards, acting either independently or conjointly, to bring about a rapid improvement.

The teaching of modern medicine is an important function. The turning out of ignorant and ill-qualified physicians is too great a menace to the community to be permitted. The only legal barrier which can protect the public from such incompetent practitioners is the state medical licensing board. There are, however, many factors which are causing confusion in standards and a serious division of responsibility. Medical licensing boards often have to contend with the inconsistency of legislatures, which, after adopting strong medical practice acts providing for fair educational standards, proceed to seriously limit the board's power by granting special legislation for various medical sects with educational standards invariably lower than those required of medical practitioners. Such special legislation has caused much confusion in standards, is unfair to medical practitioners and is a wrong to the sick and afflicted who have reason to expect that only thoroughly qualified men will have the legal right to call themselves "doctors" or "physicians."

---

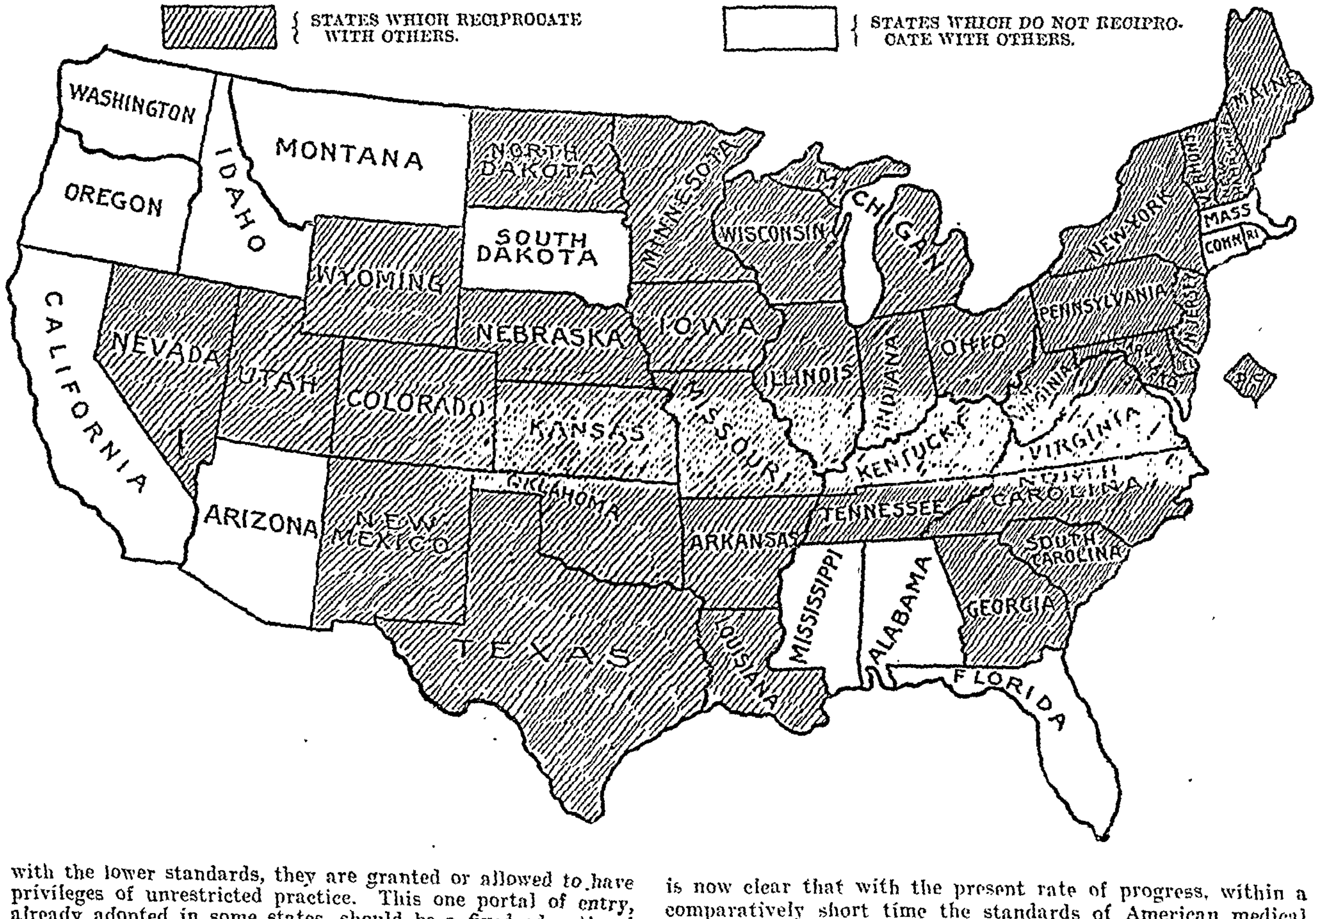
* This definition of a college is based on that given in the revised ordinances of the State of New York, and which also was adopted by the Carnegie Foundation for the Advancement of Teaching as their standard.

† Based on the definition of the term "school," adopted in 1909 by the Association of American Universities.

It is of extreme importance, therefore, that each state should have a single licensing board, that its members should be selected because of their special fitness for the work involved, and that this board should be given full authority in the premises. Instead of that we now have in our 49 states and territories 82 different boards of medical examiners including the sectarian boards. In some states the responsibility for defending the public against ignorance, incompetence and fraud, is divided among as many as four separate boards.

It is also of great importance that in each state there should be but one portal of entry to the practice of medicine. Instead of that we have in some states one portal for those with ample qualifications but special gateways by which ignorant and incompetent practitioners, professing to adhere to special methods of treatment, can also get in. In the majority of states after the representatives of these cults are licensed, even with the lower standards, they are granted or allowed *to have* privileges of unrestricted practice. This one portal of entry, already adopted in some states, should be a fixed educational standard to which all schools professing to train medical practitioners should have to comply. Graduation from a medical college holding to that standard should be required as well as the state license examination. The certificate of graduation would be *a guarantee* from a reputable medical college that the applicant has had a thorough training, since that college granted him a diploma. The license examination would furnish an added guarantee that the applicant has a knowledge of the fundamental medical sciences and the ability to recognize diseases. In testing the candidate's ability to this extent there should be no division of responsibility, no special standards, or other makeshifts. When it comes to testing the applicant's system of treatment there are numerous methods which would be effective and at the same time be fair to the applicant. For example, some boards have the authority to call in a regularly licensed practitioner of any particular school of medicine to examine in materia medica or in the applicant's special method of treatment.

CHART 3.—INTERSTATE RECIPROCITY IN MEDICAL LICENSURE



State licensing boards are fighting the people's battle against ignorance and incompetence, sometimes without the support either of the public or of the medical profession and they are often seriously handicapped. The charts herewith presented will give some idea of the conditions existing in the various states against which the licensing boards have to contend and show how necessary it is that the boards receive the undivided support of the medical profession and of the public in the important and difficult work they have to do. That some states have not already been overrun with incompetents is due entirely to the fact that examining boards have found methods by which the unfit could be excluded even with the limited authority parcelled out to them by their legislatures. The time has come, however, when the medical profession and the people of each state should see to it that a single board of competent medical examiners shall control the licensing of all practitioners of medicine and that this board be given full authority. This one barrier between the sick and afflicted and the crowds of ill-trained, incompetent practitioners should be made effective.

Very rapid and very great improvements have been made in medical education in this country in the last few years and it is now clear that with the present rate of progress, within a comparatively short time the standards of American medical education and of the American medical schools will compare favorably with those of any country in the world.

The Council believes that the coming *American standard* will be: A four-year high-school education; a year or two in the university laboratories of chemistry, physics and biology; *four* years in the medical school and a clinical year as an intern in a hospital.

About two-thirds of the acceptable schools of the country have either already put into force the requirement of college physics, chemistry and biology or will put this requirement into force this fall. This requirement, as you all know, is the one adopted by Germany, Great Britain, France and all of the advanced countries of the world. Medical educators agree that a thorough training in these branches is *practically necessary* to the student beginning the study of modern medicine.

The adoption of this requirement in some parts of the South may be somewhat delayed owing to the backward state of general education. North of the Ohio River, however, and west of the Mississippi it has already been adopted by almost all of the better schools. The members of the Council are unanimous in the belief that a degree requirement for admission to the study of medicine is too extreme to be considered in the drawing up of an American standard of medical education.

The second great advance—the addition of a clinical year—as an intern in a hospital after the completion of the work in the medical school is quite as important and in some ways more important than the requirement of the preliminary sciences for admission. This clinical year, however, is largely taking care of itself, as the modern medical student soon learns that a hospital appointment is an essential part of his medical training and makes every effort to secure it. The time will soon arrive, however, when this clinical year will be recognized as a part of the required medical course, and the whole medical curriculum will be arranged and planned with this hospital year in view.

Sixteen medical schools are now requiring as a minimum for entrance two or more years of work in a college of liberal arts in addition to a four year high school education. These colleges and the years when the requirement became effective are as follows:

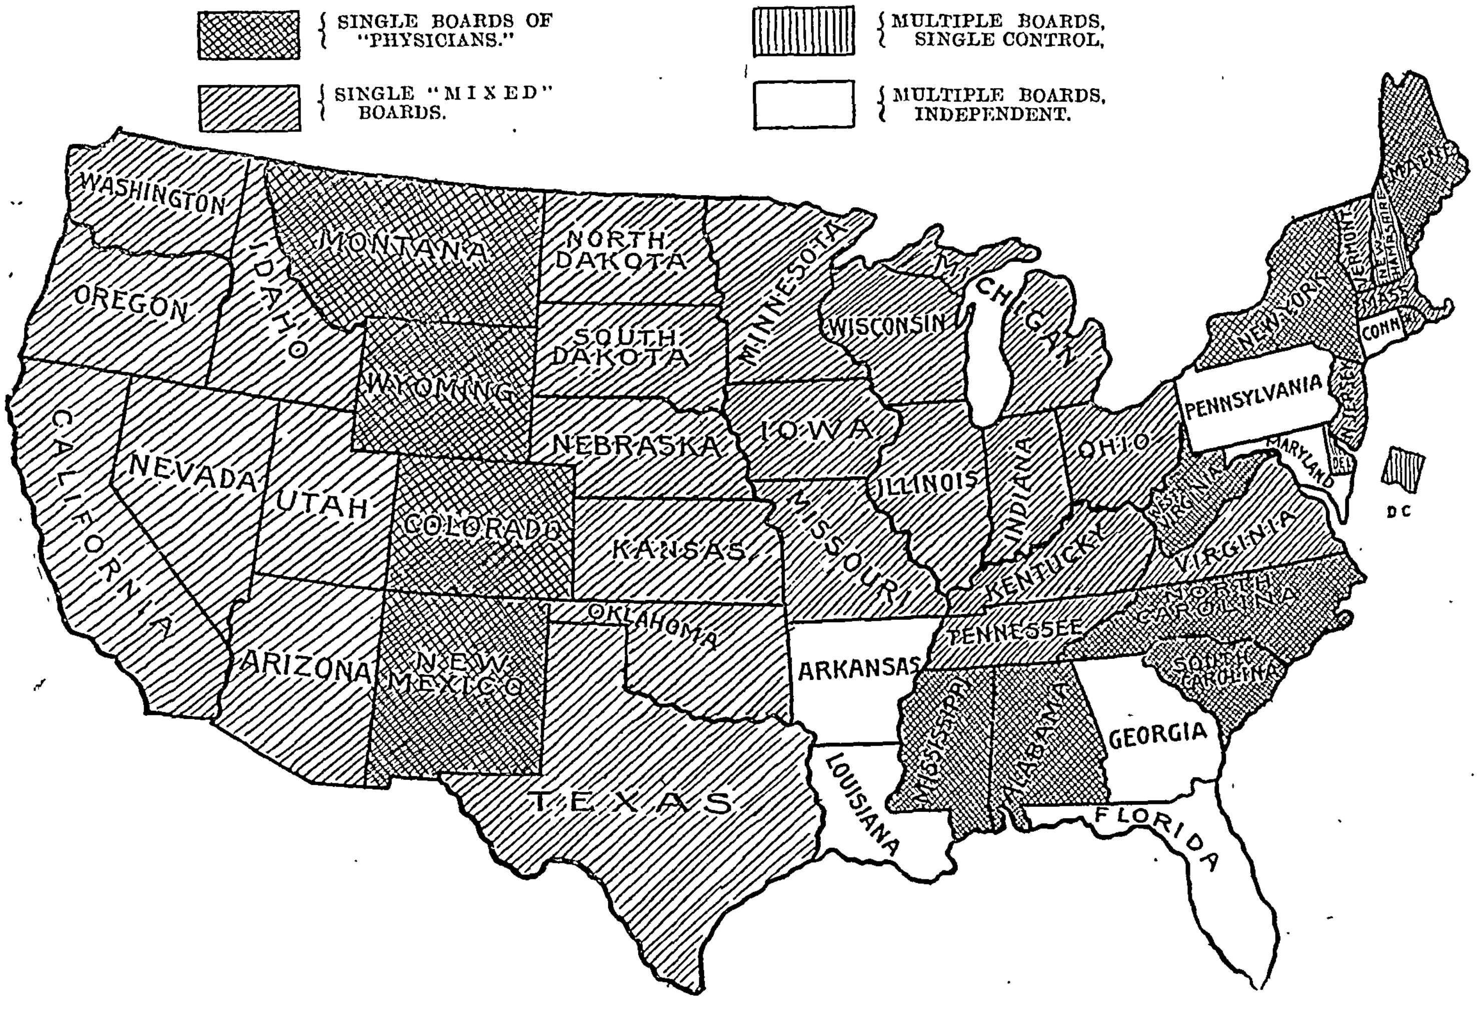
College.	Begins.
Johns Hopkins University Medical Department	1893
Harvard Medical School	1900
Western Reserve University Medical Department	1901
University of Chicago, Rush Medical College	1904
University of California, Medical Department	1905
University of Minnesota, College of Medicine and Surgery	1907
University of North Dakota, College of Medicine	1907
University of Wisconsin, College of Medicine	1907
Cornell University Medical College	1908
Wake Forest College, School of Medicine	1908
Leland Stanford Junior University, Department of Medicine	1909
Yale Medical School	1909
University of Kansas, School of Medicine	1909
University of Michigan, College of Medicine	1909
University of Nebraska, College of Medicine	1909
University of South Dakota, College of Medicine	

Ten other colleges in their printed announcements have clearly stated their intention to require two years of liberal arts' college work as their minimum standard of preliminary education for the session of 1910-11 and thereafter. These colleges are as follows:

College.	Begins.
University of Colorado, School of Medicine	1910
Indiana University School of Medicine*	1910
State University of Iowa, College of Medicine*	1910
Drake University College of Medicine‡	1910
University of Missouri, Department of Medicine†	1910
Dartmouth Medical School	1910
Columbia University College of Physicians and Surgeons	1910
Syracuse University College of Medicine*	1910
University of Pennsylvania, Medical Department*	1910
University of Utah, Medical Department*	1910

* One year required for the session of 1909-10.
† One year has been required since 1906.
‡ The printed announcement for 1909-10 contains no mention of the advance in entrance requirements but an official letter states that two years of collegiate work will be required for admission beginning September, 1910.

CHART 4.—CHARACTER OF THE STATE LICENSING BOARDS



The twenty-one following colleges either already require in addition to a four-year high school course one year of work in a college of liberal arts, including courses in physics, chemistry and biology, or have made definite statements in their printed announcements or otherwise, that they will require that standard of preliminary education in and after the year given:

College.	In Force.
Northwestern University Medical School	1908
Fordham University School of Medicine	1908
Hahnemann Medical College of the Pacific	1910
Denver and Gross College of Medicine	1910
Howard University School of Medicine	1910
Kansas Medical College	1910
Tulane University, Medical Department	1910
St. Louis University, School of Medicine	1910
University Medical College, Kansas City	1910
Washington University Medical Department	1910
Ohio-Miami Medical College, University of Cincinnati	1910
College of Physicians and Surgeons, Cleveland	1910
University of Oregon, Medical Department	1910
University of Texas, Medical Department	1910
University of Virginia, Department of Medicine	1910
West Virginia University, College of Medicine	1910
Marquette University, Medical Department	1910
Wisconsin College of Physicians and Surgeons	1912
Medical School of Maine	1912
Boston University, School of Medicine	1912
University of Vermont, College of Medicine	

Twelve other colleges sent official notices to the Council that an increase in requirements would be made. Six of these have since rescinded their action, two have been advised by the Council not to make the requirement at the present time and four others have not made clear statements of the proposed increase in their printed announcements.

For a time this elevation of standards by the better class of colleges will probably be taken advantage of by commercial, low grade colleges which will continue their lack or non-enforcement of standards in order to profit from the influx of students who are turned away from the good schools. This advantage can only be temporary, however, since, in the first place, medical students and their advisors are rapidly learning that it does not pay to spend four or five years in a college of low requirements and with standards so lax that a large percentage of their graduates fail at state license examinations, and, secondly, because state boards are coming to the support of the better colleges by adopting similar standards of preliminary education and by making their examinations of such character that they cannot be passed by applicants who have not had a training in laboratories and clinics. Such action by a considerable number of state boards will make it impossible for low-grade, inefficient medical schools to continue. Even a rigid enforcement of the four-year high school preliminary requirement would force several of these commercial schools to the wall.

At least six medical colleges have provided an optional fifth year of hospital work for which the degree of M.D. *cum laude* is granted. These colleges are:

- Boston University School of Medicine.
- Indiana University School of Medicine.
- Rush Medical College.
- St. Louis University School of Medicine.
- University of Nebraska College of Medicine.
- University and Bellevue Hospital Medical College.

The deans of at least 25 medical colleges have stated that they have more internships each year than they can fill. For these schools, therefore, the final requirement of the American Medical Association's "Ideal Standard," namely, "A sixth year as an intern in a hospital," could be easily enforced.

From the fact that 47 medical colleges have adopted higher entrance requirements it is interesting to note that seven state examining boards have also adopted preliminary requirements in advance of a four-year high school education. These are as follows:

State Examining Board of	No. of Years Required.	Affects Students Matriculating.	Affects all Applicants.
North Dakota	2	1907-08	1911
South Dakota	1	1907-08	1911
Minnesota	2	1908-09	1912
Colorado	1	1908-09	1912
Connecticut	1	1910-11	1914
Kansas	1	1910-11	1914
Indiana	2	1910-11	1914

There are several other states which are contemplating similar increases in their requirements in the near future.

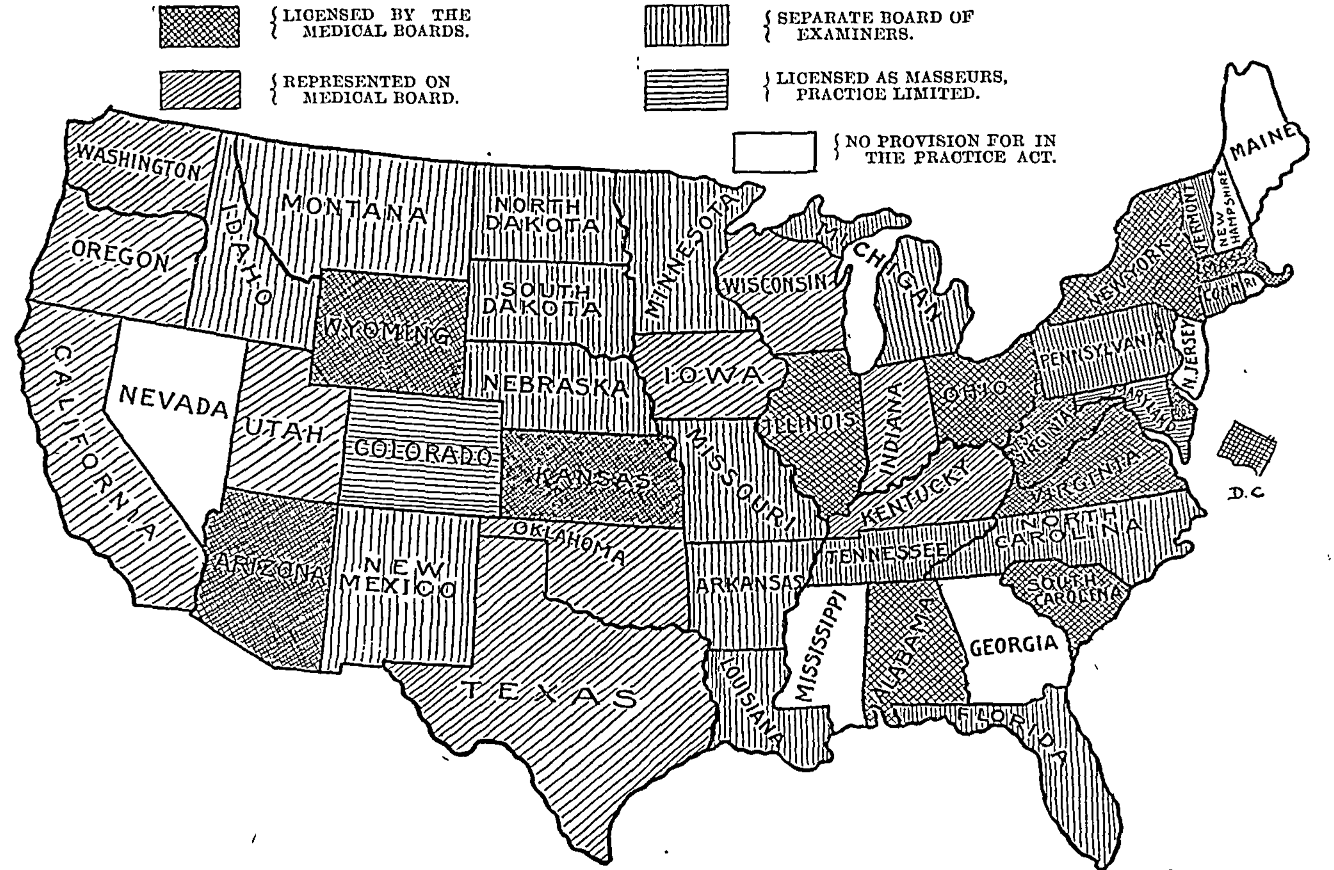
IN CONCLUSION

In conclusion it should be said that although there is still much to be done splendid progress is being made and we can all look forward to the future confident that within a few years medical education and medical licensure in this country will be on a satisfactory basis. Respectfully submitted,

Arthur Dean Bevan, Chairman.
N. P. Colwell, Secretary.

On motion of Dr. C. E. Cantrell, Texas, which was seconded by several, the House of Delegates then adjourned until 2 p. m.

Chart 5.—The Osteopathic Situation



Second Meeting — Monday Afternoon, June 6

The House of Delegates convened at 2 p. m., and was called to order by the Third Vice-President, Dr. Alexander Lambert, New York.

The minutes of the previous meeting were read and approved.

Dr. H. Bert Ellis, Chairman, made a supplementary report of the Committee on Credentials.

Dr. John G. Clark, Pennsylvania, Chairman, read the report of the Board of Public Instruction on Medical Subjects.[1]

On motion of Dr. C. S. Bacon, Illinois, it was referred to the Reference Committee on Legislation and Political Action.

The report of the Committee on Organization was called for, but by request deferred until Tuesday afternoon.

Dr. John H. Blackburn, Kentucky, presented his report as Director of Post-Graduate Work.

On motion, the report was referred to the Reference Committee on Medical Education.

---

[1] All committee reports referred to reference committees, will be published in The Journal, June 18.

Report of Committee on Ophthalmia Neonatorum

Dr. F. Parke Lewis, New York, Chairman, read the report.

To the Members of the House of Delegates of the American Medical Association:

Your committee beg leave to present the following report of legislation enacted together with a summary of the official communications received, indicating the further progress of the movement for the control of ophthalmia neonatorum throughout the United States.

ALABAMA

Ophthalmologist, Samuel L. Ledbetter; Obstetrician, W. H. Sanders; Sanitarian, W. H. Sanders.

Dr. Ledbetter introduced the subject at the meeting of the county medical society and the subject was discussed at some length but no action was taken by the society as a body. He also discussed the matter with the Senior Censor and State Health Officer who was rather opposed to taking it up with the State Medical Association, as he thought that the condition was rarely found in the country districts and small towns and that physicians and midwives in the cities seemed to understand the handling of those conditions fairly well. Besides he was, for other reasons, opposed to introducing any further medical legislation in the legislature just at the present time. Dr. Ledbetter had no suggestions to offer but will continue to agitate the matter occasionally.

ARIZONA

Ophthalmologist, Ancil Martin; Obstetrician, W. I. Simpson; Sanitarian, Gov. J. K. Kibbey.

Dr. Ancil Martin reports that nothing has been accomplished along these lines and no papers read on this subject.

ARKANSAS

[illegible]. J. W. Scales; Obstetrician, Edward Pentley; [illegible]nyan.

[illegible]: No laws pertaining to the subject of ophthalmia neonatorum were passed by our last assembly, none were introduced, no papers of any kind relating to this subject were read [illegible] our last state society meeting and none have been published in our [illegible]te journal.

Dr. J. W. Scales: There has been nothing except a resolution introduced in our society looking forward to a law to prevent blindness. Last year I attempted to get our Senator to pass such a bill.

CALIFORNIA

Ophthalmologist, H. Bert Ellis; Obstetrician, F. T. Andrews; Sanitarian, M. Regensberger.

Dr. H. B. Ellis: Our state legislature does not meet until next winter, so we have been unable to do anything in regard to laws on the subject.

COLORADO

Ophthalmologist, Edward Jackson; Obstetrician, E. A. Jayne; Sanitarian, W. H. Davis.

No report.

CONNECTICUT

Ophthalmologist, H. S. Miles; Obstetrician, H. J. Ballard; Sanitarian, Joseph H. Townsend.

Dr. Joseph H. Townsend: Nothing has been done in the state during the past year for the prevention of blindness from ophthalmia neonatorum. We had an agitation on this subject a few years ago which resulted in a law being passed by the Legislature requiring all cases to be reported by the attending physician or midwife to the local health officer. This, with our medical practice act, which is developing better educated physicians and midwives in the state, is doing all that can be done in this matter, so it seems to me. The Connecticut Board of Education of the Blind tells me that there are about ten cases of infantile blindness each year which come to their attention and about thirty per cent. of these are due to ophthalmia neonatorum. There ought not to be even this number, but I do not see that any special campaign of education would do any good or is necessary at this time. The medical profession I think, are doing all that can be done to prevent this disease as well as other puerperal infections. The conditions in this state are somewhat different from what they are in congested centers like New York and Chicago.

DELAWARE

Ophthalmologist, J. A. Ellegood; Obstetrician, F. Belleville; Sanitarian, E. W. Cooper.

J. A. Ellegood: Nothing has been accomplished in this state during the past year for the prevention of blindness from ophthalmia neonatorum. Our people are pre-occupied with the anti-tuberculosis crusade, and the medical inspection of schools. Shall hope to get some attention paid to the prevention of blindness at an early date.

DISTRICT OF COLUMBIA

Ophthalmologist, Robert Scott Lamb; Obstetrician, J. T. Johnson; Sanitarian, W. C. Woodward.

W. C. Woodward: Careful inquiry is being made into all cases of ophthalmia of infants coming to the attention of the Instructive Visiting Nurses, in order to determine whether they are of gonorrheal origin or not, and in order to determine the outcome of such cases. At the request of the health officer, the Washington Obstetrical and Gynecological Society appointed a committee, consisting of Drs. John F. Moran and W. M. Sprigg, to investigate the status of the preventive treatment of ophthalmia neonatorum, which committee submitted a lengthy report. This report was published in the February issue of the *American Journal of Obstetrics*. It was hoped, when the cooperation of the Washington Obstetrical and Gynecological Society was asked, that in event of the presentation of a report by that body recommending action by the health department, looking toward the prevention of ophthalmia neonatorum, it would be possible to adopt preventive measures. So far, however, the funds at the command of the health officer have been insufficient to permit him to do so.

Washington Obstetrical and Gynecological Society: The committee appointed by the president of the Washington Obstetrical and Gynecological Society to investigate the status of the preventive treatment of ophthalmia neonatorum begs leave to submit the following report: A circular letter was sent with the following questions to a number of maternities and obstetricians in the United States and Europe. 1. What is the routine treatment in your hospital for the prevention of ophthalmia neonatorum? 2. Would you recommend the treatment to be carried out by midwives? 3. Do you think the remedy should be dispensed by the health department?

Forty replies were received and are tabulated below. All employ prophylactic measures, but differ in the choice and strength of the solution, technic, regulation of midwives, and the advisability of the health department dispensing the drugs.

Twenty-three used silver nitrate: one, ½ per cent.; ten, 1 per cent.; two, 1½ per cent.; nine, 2 per cent.; and in one the per cent. is not given. Fifteen use argyrol; one, 5 per cent.; one, 6 per cent.; one, 16 per cent.; one 10 to 20 per cent.; four, 20 per cent.; five, 25 per cent.; one, 25 to 50 per cent.; one, 50 per cent.; and in one the per cent. is not mentioned. Five employ sophol; all, 5 per cent. One prefers silver acetate, one per cent; another, hydrarg. bichlor., 1-2000. Protargol is used by four, but supplementary to nitrate of silver in three, hydrarg. bichlor. in one.

The questions 2 and 3 were only submitted to hospitals in the United States, and there were thirty-one replies; twenty-five favored the use of prophylactics by midwives, but several advise that the midwives be taught the proper methods of application, while others recommend that only the substitutes for silver nitrate be employed by them. It is observed that those quoted in this report who oppose the treatment by midwives all use silver nitrate and one of the objectors states that the drug is too powerful and dangerous to be entrusted to the uninitiated.

In reply to question 3, twenty recommend that the prophylactic be dispensed by the health department, while eleven object, one regarding it as another socialistic measure.

It is worthy of note that only 60 per cent. of the institutions quoted use silver nitrate exclusively. These figures were received from widely separated sources and may reasonably be taken as a fair index of the trend of the prophylaxis of ophthalmia in the new-born.

A review of the literature shows that in this country silver nitrate, argyrol, and protargol are the remedies generally employed as prophylactics; while abroad, in addition to these, argonin, collargol, albargin, itrol, sophol, largin, silver acetate, etc., have been employed and recommended. Stephenson says that some of these have already sunk into well-merited oblivion, but others are calculated to replace silver nitrate at no distant day.

Argyrol is rapidly growing in favor, is largely used in private practice, and has been introduced into many hospitals. According to Cragin a 25 per cent. solution is equally as effective as one of 2 per cent. silver nitrate in gonorrheal ophthalmia, does not cause pain or produce irritation, and has the important advantage that it can be applied by the nurse, midwife, or layman without danger. He says, however, it is of comparatively little value in staphylococcus and streptococcus infections. In his service at the Sloane Maternity, in 8,000 births, covering a period of seven years, he used as a prophylactic measure five methods of treatment, with a view of selecting a solution that would give the greatest amount of disinfection with the least irritation. The results were as follows:

Series 1—In 1,000 confinements, 2 per cent. silver nitrate solution; cases of ophthalmia, thirty-four; eyes lost, one; opacities, none.

Series 2.—In 1,000 confinements, 1 per cent. silver nitrate solution; cases of ophthalmia, thirty-four; eyes lost, one; opacities, none.

Series 3.—In 2,000 confinements, 5 per cent. protargol solution; cases of ophthalmia, thirty-four; eyes lost, one; opacities, two.

Series 4.—In 2,000 confinements, 10 per cent. argyrol solution; cases of ophthalmia, thirty-four; eyes lost, one; opacities, two.

Series 5.—In 2,000 confinements, 20 per cent. argyrol solution; cases of ophthalmia, thirty-nine; eyes lost, none; opacities, none.

This series covered a period when there was an epidemic of "pink eye" in the city, and as no gonococci were present in the eyes during the month of its prevalence it was thought by the ophthalmologist who saw the cases in consultation that they were cases of pink eye.

Cragin says that while with the use of 1 per cent. silver nitrate solution and 5 per cent. protargol solution there was less irritation, it looked as if it was gained at the expense of protection, and their use was therefore abandoned. With the 10 per cent. argyrol solution there was a complete absence of irritation, but it was found upon clinical and bacteriological investigation to be of insufficient strength, and therefore did not afford complete immunity.

The 2 per cent. silver nitrate solution and the 20 per cent. argyrol solution were proven to be absolutely bactericidal, and the latter is to be preferred because of its freedom from irritation and it can be applied at frequent intervals, if necessary, with safety.

We have collected from the records of Columbia Hospital, Washington, D. C., from 1882 to June, 1909, 205 cases of ophthalmia, occurring in 7,236 confinements; 176 cases were reported as cured and twenty-seven were improved at the time of leaving the hospital, so the final result of the latter is not known. There were two cases of blindness; one, total; in the other one eye was lost. There were five cases with opacities of one cornea and one with opacities of both corneas. The earlier records are wanting in microscopical examination, but clinically a large percentage of primary ophthalmia were diagnosed as gonorrheal, with the infections occurring some days after birth generally ascribed to other pathogenic organisms. In 1904, argyrol was introduced, first using a 10 per cent. solution, but as this did not prevent ophthalmia, it was increased to 25 per cent. There had been no cases of blindness or opacities since its introduction.

Professor Zweifel speaks enthusiastically of the acetate of silver in the prevention of ophthalmia neonatorum. In a letter recently received from him, he says that in fourteen years' experience with the drug, blennorrhea occurred in only about 0.02 per cent. of the cases. Irritation is not more frequent or greater than with 1 per cent. of nitrate of silver, as was demonstrated by using the silver nitrate in one eye and the silver acetate in the other. Seitz has obtained a like favorable result in 1,000 births in the Numchen Frauenklinik and Scipiades in the Traufferschen Klinik, Budapest.

Darier and his pupil, Valencon, are warm advocates of protargol. They employ it in 15 to 20 per cent. solution and find it to be less painful and irritating than silver nitrate.

Englemann, using protargol, in the Bonner Frauenklinik, observed 20 per cent. of the infection, usually of mild character, in 1,000 births.

Piotrowsky, in the Hebammenlehranstalt, Krakau, noted 10 per cent. reaction in the treatment of 1,030 cases after the use of a 10 per cent. solution of protargol.

V. Herff, in the Frauenspitale, Basel-Stadt, in 3,000 births, with the use of protargol, had only two late infections but there was 30 per cent. primary reaction.

V. Herff, in endeavoring to find a substitute for silver nitrate possessing equal germicidal power but free from its objectionable properties, first tried protargol. While, as just stated, there were no primary infections, he discarded it because of the large percentage of inflammatory reactions. He next tried argyrol, in 520 births, but not being entirely satisfied, he experimented with sophol. It is a combination of formaldehyd nucleinic acid, and 22 per cent. silver. Sophol is a yellowish-white powder, easily soluble in water. The solution must be prepared with cold water, as a warm solution dissociates the loose combination of the formaldehyd in the preparation. In over 6,000 births, V. Herff says there were one primary and one late infection. The early case of infection was due to inoculation in a known gonorrheal case during labor, in which a prolapse cord was replaced. The late infection occurred on the ninth day in an infant whose mother was suffering with *condylomata of the* vulva. There was 10 per cent. primary reaction, usually of a mild character..

In 1,436 births in which sophol was used, in the Munchener Frauenklinik, there were one primary infection (0.07 per cent.) one late infection (0.07 per cent.) and three cases of inflammatory reaction of mild intensity.

[illegible] 1909, Menge has employed sophol in the [illegible] Heidelberg. The sophol solution has [illegible] eye of the infant, and a 1 per cent. silver nitrate solution into the right eye. He finds that irritation occurs less frequently with sophol. Two cases of true blennorrhea, both late infections, have occurred this year, both in the second week. The left eye was infected in one infant and the right eye in the other.

Callatia reports the use of sophol as a prophylactic in 280 births in the Landenspitales, Laibach. There was no early infection, notwithstanding that two of the mothers were suffering with gonorrheal vaginitis at the time of delivery.

Bock and Kraus have also used sophol in inflammatory diseases of the eyes with excellent results. Bock finds it to be particularly effective in recent cases; but in those of long standing, while it rapidly diminishes the discharge, in many instances it is necessary to resort to the use of silver nitrate to effect a cure.

The committee being much impressed with the excellent results obtained with sophol by V. Herff and others was anxious to give it a trial. Through the courtesy of Dr. Cabell, of the visiting staff of Columbus Hospital, and Dr. Lawson, of the visiting staff of Freedman's Hospital, the remedy was used in these institutions during the past summer. A 5 per cent. solution was employed, and it was freshly prepared every two weeks. Altogether the solution was instilled into the eyes of 153 infants, ninety-three in Columbia Hospital, and sixty in Freedman's Hospital. Of those treated at Columbia Hospital, there were thirteen with primary irritation, lasting from a few hours to several days, all yielding to boric acid irrigation. There was no primary infection, although one mother had been under treatment in the hospital for more than a week prior to the delivery for a severe case of gonorrheal vulvovaginitis. The infant's eyes were wide open immediately after birth and had a dull glazed appearance, with clouded cornea. Prompt instillation was made and no infection followed.

There were eight late infections, occurring from the third to the fourteenth day after birth. Six yielded to the sophol and boric acid applications in from a few hours to eight days. One case in which the lanceolatus was found left the hospital on the eleventh day of treatment, improved; and another in which the microscopical examination was negative left also on the eleventh day of treatment improved.

Dr. Lawson reports that sixty infants received the 5 per cent. sophol solution at birth in Freedman's Hospital, and the results were very satisfactory. In but one case was there anything more than a slight inflammatory reaction observed. One baby developed a purulent conjunctivitis, which was slight and cleared up within five days, during which time the sophol solution was instilled three times daily. The mother in this case had a marked vaginal discharge at the time of confinement.

Our personal experience with the use of sophol is in accord with that of other investigators and we regard it as a safe and effective measure for the prevention of ophthalmia neonatorum.

In conclusion, the committee recommends: 1. That immediately following the birth of the infant the eyes should be carefully wiped with sterile gauze, dipped in a saturated solution of boric acid and then a 5 per cent. sophol, 25 to 50 per cent. argyrol, or 10 to 20 per cent. protargol solution used as a prophylactic against ophthalmia neonatorum.

Since late infections comprise one-fourth of the cases of ophthalmia neonatorum and may be due to the faulty application of the prophylactic, or latent gonorrhea, but is more often the result of contamination from the vaginal secretion because of lack of vigilance, or ignorance on the part of attendant or mother; therefore the nurse should be instructed to thoroughly scrub her hands with soap and water and disinfect them before washing the *infant's* eyes, dressing the navel, and bathing the mother. The mother's hands should be cleansed several times daily, particular attention being given to the nails, and she should be repeatedly warned as to the danger of the lochia. By careful attention to these precautions the morbidity from ophthalmia can be greatly reduced it not entirely controlled.

2. That the solution be dispensed in amber-colored sterile tubes sealed with paraffin for use by midwives; a small quantity of sterile gauze be placed in the prophylactic package.

3. That suitable instructions as to technic be printed on the birth certificates.

4. That legislation be enacted for the control of midwives.

5. That midwives be compelled to make report of births within 24 hours following delivery.

6. That the health department furnish the drugs gratuitously to indigent cases.

7. That in cases of ophthalmia occurring in patients under the charge of midwives they be required to summon a physician immediately or notify the health department promptly.

Finally what is need to control this scourge is a hearty cooperation of the medical profession with the health authorities.

FLORIDA

Ophthalmologist, Columbus Drew; Obstetrician, E. N. Liell; Sanitarian, Joseph Y. Porter.

Dr. C. Drew: At the annual meeting of the Florida State Medical Association, held April 6, resolutions were adopted endorsing the work of the American Medical Association in its efforts to prevent blindness from ophthalmia neonatorum, requesting the state board of health to cooperate with the American Medical Association in this work, requesting the local societies also to cooperate, and appointing a committee of three (Dr. C. Drew, Jacksonville, Dr. E. N. Liell, Jacksonville, Dr. Dewitt Webb, St. Augustine) to facilitate the work during the year and to report at the annual meeting of the state association in 1911.

Joseph Y. Porter: The state board of health of Florida has not as yet undertaken any work in this direction. The importance of the subject as a public health problem is [illegible] and it is not unlikely that an effort will be m[illegible] ture to [illegible] of the midwives [illegible] ightful menace to sight— eyes of [illegible] ophthalm[illegible] of that character which may be [illegible]

GEORGIA

Ophthalmologist, H. H. Martin; Obstetrician, F. C. Hodgson; Sanitarian, H. F. Harris.

H. H. Martin proposed a law which provides for the compulsory use of a *prophylactic by midwives and others* and an addition to the birth certificate stating whether or not a prophylactic had been used, the character of the prophylactic being left to the physician. The legislature was asked to secure the enactment of such a law.

IDAHO

Ophthalmologist, Charles R. Hugel.
No report.

ILLINOIS

Ophthalmologist, W. H. Wilder; Obstetrician, C. S. Bacon; Sanitar[illegible] to Inquire into the Condition of th[illegible] *State Board of Charities*, held Ju[illegible] appointed to inquire into the condit[illegible] h a view to formulating plans for the employment of the adult blind and for improving the efficiency of the state care in other particulars. The following were appointed: Clara P. Bourland, of Peoria, chairman, and Dr. John T. McAnally, of Carbondale, representing the State Board of Charities; Geo. W. Jones, superintendent Illinois State School for the Blind, Jacksonville; C. D. Babb, of Homer, trustee of the State School at Jacksonville; Joseph F. Otis and E. J. Nolan, of Chicago, trustees of the Illinois Industrial Home for the Blind at Chicago; Mr. [illegible] blind people in Illinois; Mrs. Alice E. Bat[illegible] go Woman's Club; Dr. Wm. M. Wilder, of [illegible] *Illinois Charitable Eye and Ear Infirm*[illegible] M. Dawes, representing the Chicago Boa[illegible] Elmer E. Hagler, of Springfield, represen[illegible] *ical Society*.

The first meeting of the commission was held in Jacksonville, September 17, at the school for the blind, Mrs. Bourland presiding; Dr. E. E. Haglor was elected secretary. Professor Wilder addressed the commission, and, from statistics presented, demonstrated that from 40 to 45 per cent. of all cases of blindness were absolutely preventable; and notwithstanding that fact, blindness is increasing in all civilized countries. The largest amount of blindness, he said, comes from ophthalmia neonatorum, or blindness of the new-born. This disease, which is easily preventable, causes from 25 to 30 per cent. *of all cases of blindness. Dr. Wilder also called attention* to the prevalence of trachoma in the southern part of the state. Following his lecture, Dr. Wilder held an informal clinic, exhibiting chiefly children in the school who were suffering from the results of ophthalmia neonatorum and trachoma.

A sub-committee of three was appointed, to report at the next meeting, consisting of Dr. Wilder, who is to report suggestions for the prevention of blindness and to recommend the enactment of needed laws; Mr. Jones, to report of the needs of his school and to recommend more efficient legislation; and Mr. Nolan, to make recommendations and suggest such laws as will improve the conditions surrounding the employment of the adult blind.

The second meeting was held in Chicago at the Industrial Home for the Blind, Saturday, December 5.

The sub-committee, consisting of Messrs. Nolan, Jones, and Wilder, made their reports. Dr. Wilder, in his report, stated, that as the state has assumed the responsibility of custodian of the blind poor and may, because of unfavorable circumstances, have more of such afflicted persons thrown on its charge, it should endeavor to study the causes of blindness and if possible seek out means for its prevention. To this end, it is important to collect statistics as to the prevalence and degree of blindness, and so far as possible the exact cause of it in each case.

Dr. Wilder, Dr. McAnally, and Dr. Babb were made a committee to prepare specific recommendations on the prevention of ophthalmia neonatorum. Their report follows:

It is well known that ophthalmia neonatorum is the cause of a large proportion of blindness in this as well as other countries, and that in the specific schools for the blind as many as 25 per cent. to 35 per cent are there because of this disease. It is also a well established fact that by proper and comparatively simple means it may be prevented in a vast majority of cases.

The state should enact a law having for its object the adoption of measures for the prevention of this disease at least in the practice of midwives and in public institutions where obstetric cases are treated..

The state board of health seems to be the proper authority for establishing the necessary rules, regulations and ordinances and enforcing their observance, and for publishing and distributing appropriate information and instruction on the subject.

It is probably best that the specific method to be used for the prevention of ophthalmia neonatorum should not be left to the intelligence and judgment of the state board of health, believing that it will act in accordance with the most advanced existing knowledge. The following form of law is suggested in accordance with the ideas suggested above.

"An act to prevent inflammation of the eyes of the new-born babe, or so-called ophthalmia neonatorum.

Section 1.—The board of health of the state of Illinois is hereby vested with power and authority to publish and distribute such information and instruction, to furnish such remedies and to make such rules, regulations and ordinances as it may deem expedient to prevent the development of inflammation of the eyes of the new-born babe, so-called ophthalmia neonatorum, *in* public hospitals or institutions in which midwifery is practiced, either wholly or in part, and in connection with the practice of midwives.

Section 2.—*Said board of health* is authorized to enforce its rules, regulations, and ordinances on this subject at the expense of the state.

Section 3.—Any person violating any rule, regulation or ordinance of said board of health *regarding the prevention* of ophthalmia neonatorum shall be guilty of a misdemeanor, and shall be punishable by a fine not to exceed $100, or imprisonment not to exceed six months, or both.

The above suggestions are in substance *embodied in the* report of the Committee of the American Academy of Ophthalmology and Oto-Laryngology cooperating with the committee of the American Medical Association on legislative measures to prevent ophthalmia neonatorum, presented to the house of delegates of the American Medical Association, June, 1908.

The central feature of giving the state board of health direction of the whole matter and power to act is, in our judgment, a good one. A law similar in purposes to the one proposed would be more effective than the one now on the statute books (Chap. 38, Sec. 510, Revised Statutes of Illinois) relating to the same object, which by the new enactment could be repealed.

According to the present law, which, so far as I am aware, is not enforced, the nurse or midwife who notices a discharge from the eyes of an infant within two weeks after its birth must report the same to a health officer of the town, or some legally qualified practitioner, within six hours of the discovery, under penalty for failure to do so. The proposed new law contemplates that the midwife shall be instructed by the state board of health in the method of prophylaxis, which she will be compelled to use in every case, and in addition that she will report any cases of the disease that may arise in her practice, to the proper authorities.

INDIANA

Ophthalmologist, Albert E. Bulson; Obstetrician, T. B. Eastman; Sanitarian, J. N. Hurty.

The legislature has not been in session this year, so nothing in a legal way has been accomplished. The subject is being given wide publicity, however. The state board of health has been very progressive in its efforts to further the cause of preventive medicine, including the prevention of ophthalmia neonatorum, although they are not, at the present time distributing silver of nitrate solution. The Tippecanoe county medical society has taken up the matter and are sending out the following circular letter to the various medical societies in Indiana. The next birth certificates will have upon them the recommendations of the committee of the American Medical Association.

Circular sent out by the Medical Society. Because institutions for the instruction of the blind (which keep accurate data, concerning *the cause of the blindness of their pupils)* report about thirty-five per cent. of their pupils to be blind as the result of ophthalmia neonatorum, the Tippecanoe County Medical Society, by its committee on ophthalmia neonatorum, asks the cooperation of the profession, *by county and district society action and otherwise,* in a propaganda looking to the abolition of the disease in this state.

We *recommend that the widest publicity be given the* Credé method, which consists in dropping into each eye of the new-born babe, *by the physician, one drop of a 1 per cent. solution of silver* nitrate, as soon as possible after the birth of the baby's head and the cleansing thereof.

We recommend cooperation of all societies to secure of the next legislature the passage of a law as will best stamp out this preventable disease, and save eyes otherwise doomed to destruction.

We recommend that each county and district society appoint a committee on ophthalmia neonatorum in order that it may in its own county use its influence with the profession and public in eradicating this disease.

We recommend that each county and district society take action, endorsing this propaganda, and that such action be reported to the undersigned committee not later than May 15, that the Committee of the American Medical Association on ophthalmia neonatorum may be informed as to the progress made in this state as to the above actions. Said committee will report its progress to the next meeting of the American Medical Association, the first week in June.

Fraternally submitted.

GEO. E. KEIPER, Chairman;
EARL VAN REED,
President, Tippecanoe Co. Society;
W. N. RESER, Secretary;
PROF. SEVERANCE BURRAGE.

....

The ———— County Medical Society hereby endorses the propaganda of the Tippecanoe County Medical Society, looking to the abolition of ophthalmia neonatorum in Indiana.

President, ...
Secretary, ...

IOWA

Ophthalmologist, E. R. Lewis; Obstetrician, W. B. LaForce; Sanitarian, F. W. Powers.

E. R. Lewis, Symposium: Ophthalmia Neonatorum in Iowa, with *a consideration* of State Prophylaxis: Last year the Iowa State Medical Society, in common with most other state *medical societies,* appointed a committee to take up the matter of the prevention of ophthalmia neonatorum in the state. It has seemed *advisable* to this committee to recommend taking steps to secure accurate and complete data in regard to this disease in Iowa, *for* the obvious reason that up to the present we have had no means of ascertaining anything definite concerning it. If state prophylaxis is adopted and the taxpayer pays the bills, even though they be small ones, he should also be provided with a means *of comparing* results and of knowing whether or not the disease is being stamped out. Should future agitation bring into *question* the advisability of giving up state prophylaxis of this disease the data concerning the disease would at once furnish accurate *proof* of the failure or success of the preventive measures. The means of securing this data is already in our hands, in the birth certificate. It is necessary only to add a few lines to the birth certificate already in use. The requiring of attendants to record such data on the birth certificate would not only be the means of assembling statistics concerning the disease, it would also be a very practical means of enforcing attention on the part of the attendants *to prophylactic* measures. The fear of consequences, should failure to use prophylaxis be followed by the disease, would do much to prevent *neglect* of proper care of the eyes at birth.

Revocation of license *to practice should be the penalty* for repeated neglect to use prophylaxis or for false entries on the birth certificate.

Very effective work has been accomplished in the state of Iowa.

KANSAS

No report.

KENTUCKY

Ophthalmologist, F. Manning Brown; Obstetrician, L. S. McMurtry; Sanitarian, Jos. M. Mathews.

No. report.

LOUISIANA

Ophthalmologist, H. Dickson Bruns; Obstetrician, S. M. D. Clark; Sanitarian, C. H. Irion.

Symposium on *ophthalmia* neonatorum was read by Dr. E. A. Robin, Dr. N. Feingold, Dr. Robert Salter and Dr. Dickson, before the County Medical Association. The papers were amplified and read at the meeting of the Louisiana State Medical Society and were to be *published among the transactions of the* society in the New Orleans *Medical and Surgical Journal,* after which they will be *acted upon by the state and city boards of health.*

MAINE

Ophthalmologist, E. E. Holt; Obstetrician, Fred W. Mann; Sanitarian, A. G. Young.

No new action has been taken during the past year for the preventation of blindness. However, the following act appears upon the statute books: Chapter 18. Prevention of Blindness. Section 90. If one or both eyes of an infant become reddened or inflamed at any time within four weeks after birth, the midwife, nurse or person having charge of said infant shall report the condition of the eyes at once to some legally qualified practitioner of medicine of the ctiy, town or district in which the parents of the infant reside. Any failure to comply with the provisions of this section shall be punishable by a fine of not to exceed one hundred dollars, or imprisonment not to exceed six months.

MARYLAND

Ophthalmologist, Hiram Wood, M.D.; Obstetrician, W. A. B. Sellman; Sanitarian, Wm. H. Welsh.

Nothing of importance has been accomplished. Several public addresses have been delivered by Dr. Hiram Woods on the general subject of prevention of blindness and especially ophthalmia neonatorum. *He advised changes providing for educating midwives and* licensing them. 2. Better birth registration. 3. Systematic instruction, by *the society for prevention of blindness of present midwives* who are exempt under the new law. 4. Compulsory prophylaxis for Baltimore later.

An excellent midwifery bill has been adopted by the legislature of the state of Maryland. It provides for the issuing of a license without examination to those actually practicing on the first of July, 1910, before the passage of the law, for all others an examination is required before a license shall be issued. It is required that the applicant shall, at least, know how to read and write and make out a birth certificate correctly, as required by law. The state board of health has charge of the details of the examination. It is also required that the candidate shall have attended at least five cases of child birth and is competent to attend ordinary cases of labor. The former law providing a penalty for the failure to report the existence of the symptoms of ophthalmia neonatorum remains unchanged. It is the first step *toward the elimination of* the midwife evil.

MASSACHUSETTS

Ophthalmologist, Myles Standish; Obstetrician, D. H. Craig; Sanitarian, Henry P. Walcot.

A most valuable paper by Dr. Mark Richardson, entitled Ophthalmia Neonatorum; Facts Concerning the Disease and its Prevention as Affecting the State of Massachusetts was read before the associated boards of health of Massachusetts and later published in the *American Journal of Public Hygiene.* The effect of these official actions are best studied in the following table kindly furnished by Dr. S. H. Durgin, chairman of the Boston board of health.

REPORTED CASES OF OPHTHALMIA NEONATORUM IN BOSTON

Year		Cases reported	Treated in hospitals	Brought from other cities
1905	(from Sept. 5)......	16	3	..
1906	....	34	13	1
1907	....	17	7	..
1908	....	39	31	2
1909	....	171	115	30

All cases of *ophthalmia neonatorum reported* and not already under treatment in hospitals are seen by a medical inspector and if *proper care cannot be secured* in the home the case is sent to the hospital.

The records of the state board of health show no cases reported in 1905, 1906, or 1907; 20 cases in 1908 and 100 cases in 1909. *There can* be no doubt that the large increase in reported cases in 1909 was due to the action of the state board of health in putting the disease on the notifiable list, in sending to each practitioner a communication calling his attention to the law and in giving him detailed information concerning treatment. It is, of course, too early to estimate the effect upon the aggregate blindness of the state. The state board of health of Massachusetts has under consideration, the free distribution *of the prophylactic.*

The conclusions at which Dr. Richardson arrives are:

1. The cause of *ophthalmia* neonatorum and the manner of its spread are known.
2. *Reliable* methods of preventing the disease are known.
3. The law in Massachusetts is such that the disease, if promptly *reported may* still be deprived of many of its destructive effects through energetic cooperation of local and state health authorities.
4. Improvement in conditions is, undoubtedly, going on, but it is slow. Rapid change for the better can be *obtained only through* a sharp appeal to the self-interest of the practitioner. There can be little doubt that vigorous *enforcement of the law concerning*

notification, with or without resulting convictions, would, through the publicity alone, impress the importance of this matter upon the profession to an extent possible in no other way.

5. The practice of midwives in Massachusetts is extensive and without supervision. They should be regulated or suppressed.

In July of 1909 an important circular was issued by the Board of health in which attention was called to the revised laws. The following paragraphs are italicized: "Should one or both eyes of an infant become inflamed, swollen and red, and show an unnatural discharge at any time within two weeks after birth, it shall be the duty of the nurse, relative or other attendant having charge of such infant to report in writing within six hours thereafter, to the board of health of a city or town in which the parents of the infant reside, the fact that such inflammation, swelling and redness of the eyes and unnatural discharge exist. On receipt of such report, or of notice of the same symptoms given by a physician as provided by the following section, the board of health shall take such immediate action as it may deem necessary in order that blindness may be prevented. Whoever violates the provisions of this section shall be punishable by a fine of not more than one hundred dollars.

"If one or both eyes of an infant whom or whose mother he is called to visit become inflamed, swollen and red, and show an unnatur[illegible] o weeks after the birth of such infant, he [illegible] notice thereof in writing over his own sigr[illegible] or board of health of the town; and if he refuses or neglects to give such notice he shall forfeit not less than fifty nor more than two hundred dollars for each offense."

It also includes suggestions for the prevention and treatment of ophthalmia neonatorum as prepared by the Massachusetts Medical Society. This is of such importance as to be given in full as follows:

"Ophthalmia neonatorum is an inflammation of the eyes of the new-born, which is usually due to infection by a specific organism. If not properly treated, blindness is a very common result. A large proportion of the blind babies owe their loss of sight to this cause. Blindness rarely occurs if the disease is properly treated from the beginning. The possibility of any baby becoming infected at the time of confinement should be constantly borne in mind, and it is desirable to carry out a routine treatment in every case.

PREVENTIVE TREATMENT

1. After washing the lids and adjacent tissues, drop into the eye of every new-born babe a few drops of a 25 per cent. solution of argyrol or a 5 per cent. solution of protargol.
2. It is not necessary to wash the solution from the eyes, as it is practically non-irritating.
3. Care should be taken that the end of the dropper does not touch the eye-ball, and that the finger-nails do not come in contact with the cornea.
4. The solution of argyrol or protargol should be freshly prepared for each confinement case.

SUGGESTIONS

Before leaving a confinement case, the physician should instruct the nurse, of, if a nurse is not employed, the most intelligent member of the family, to notify the doctor at once if the eyes become inflammed and discharge matter. He should also call attention to section 49 of chapter 75 of the Revised Massachusetts Laws.

2. When possible these cases should be placed in the hands of an occulist. It is extremely desirable that all cases met with among the poorer classes be transferred at once to the Massachusetts Eye and Ear Infirmary, or some similar institution in the city where they occur. This is advisable, not only for the good of the child, but for the safety of other members of the family as well. For the fact must not be lost sight of that the disease is very contagious, and that, if the eyes of an adult or older child become infected, it means an inflammation of even greater seriousness than when present in the eye of the new-born babe.

3. If circumstances make it necessary that the child be treated at home, the serious and infectious nature of the disease should be impressed upon the family. The baby should be separated from the other children. Caution should be given to those having the care of the child that their hands should be frequently washed and not brought in contact with their own eyes. All bits of cotton used about the eyes should be carefully separated and thoroughly boiled.

4. The following treatment should be begun at once. Wash the eyes every forty minutes with a 3 per cent. boric acid solution. This requires the services of two intelligent persons, preferably nurses, one for day and the other for night duty. They should be carefully instructed that in cleansing the eyes the inner angle and edges of the lids, which are usually tight shut, should be freed from discharge by means of a bit of absorbent cotton wet with the solution. It the lids are then separated most of the retained secretion will escape and what remains can easily be dislodged by taking another bit of cotton, thoroughly saturated with the solution, holding it an inch or two above the eyes, and then by pressure causing a stream to flow gently into the conjunctival sac. The lids should be dried after each washing, and four or five times a day, it is well to apply a little simple ointment to their edges. Nurses or attendants doing this work should have their finger-nails trimmed as short as possible, for if a slight abrasion of the cornea be made in the process of washing the eyes or separating the lids, it will be quickly followed by infection and ulceration. The danger of the baby scratching the cornea with its finger-nails should also be prevented by confining the hands.

Next in importance to cleanliness is the use of some silver salt. A 25 per cent. solution of argyrol or a 5 per cent. solution of protargol may be used freely every four hours, the eyes to be first freed from secretion. In applying the remedy, the child should be placed flat on the back, and the head so held that the solution will not quickly escape from the eyes. The lids being separated with the thumb and finger, a few drops should be instilled with an eye-dropper. Careful instructions should be given, however, that the end of the dropper be not brought in contact with the cornea, or the instillation made with too great force. This treatment, frequently cleansing the eyes and the use of argyrol, or protargol, if it can be thoroughly and systematically carried out, will, with rare exceptions, ensure a perfect recovery.

MICHIGAN

Opthalmologist, W. R. Parker; Obstetrician, J. H. Carstens; Sanitarian, Angus McLean.

Dr. J. H. Carstens: I can find no papers on the subject of ophthalmia neonatorum. I personally, have had a number of talks with our health officer. The trouble with enforcing the law is the ignorance of midwives and we now have a proposition before the aldermen to put them under the control of the health board. We will gradually get this under control.

Dr. Walter R. Parker: For various reasons it has not seemed advisable to make a frontal attack just at present. I have not missed an opportunity to bring the matter up. Have a talk in Ann Arbor to-morrow night before the Young Men's Christian Association. I believe a little more educational work is necessary before the professional men will take it up in earnest. I think, however, that next year the whole matter can be brought up before the society in a way that would be more effective and produce better results than to attempt anything at the present time.

MINNESOTA

Ophthalmologist, Frank C. Todd; Obstetrician, A. B. Cates.

An important symposium was presented at the forty-first annual meeting of the Minnesota Medical Association, held at Winona, October 14 and 15, 1909. A comprehensive and valuable paper was read by Frank C. Todd, entitled Unnecessary Blindness, and one on Etiology and Prophylaxis of Ophthalmia Neonatorum, by Jennings C. Litzenburg, of University of Minnesota. Resolutions to accomplish the ends sought were passed by the association and at the proper time an effort will be made to obtain legislation upon the subject.

MONTANA

[illegible] hn A. Donovan; Obstetrician, D. Campbell; [illegible]

[illegible] Year before last the question occupied the greater portion of the time of the public heal[illegible] tions were adopted relative to the nature of [illegible] and were sent to the legislature of our state. [illegible] in the hope of securing some legislation on thi[illegible] killed.

Dr. Donald Campbell: Nothing has been done in our state the past year. Our state society meets in May and we hope to get some resolutions passed, then, if nothing else.

MISSISSIPPI

Ophthalmologist, Jas. B. Bullitt; Obstetrician, J. C. Blackstrom; Sanitarian, B. F. Ward.

Dr. James B. Bullitt: The past year has shown some progress in Mississippi in this fight, but not nearly so much as might be desired. No papers have been read before any large gatherings but there have been a number of papers and a good many talks made before the various county medical societies. The committee on legislation of the State Medical Association, in cooperation with the state board of health, has made a strong effort to pass a bill this winter, looking toward the accurate collection of vital statistics, including ophthalmia. The bill failed to pass but some progress was made toward educating some of the legislature along this line, and we hope will bring some results at the next meeting.

MISSOURI

Ophthalmologist, P. I. Leonard; Obstetrician, T J. Beattie; Sanitarian, E. S. Ballard.

A paper entitled The Prevention of Ophthalmia Neonatorum was read in May, 1909, and published in the August number of the *Journal of the Missouri State Medical Association*. The following law is now upon the Missouri statute, but is not enforced.

Section 7530.—Midwife to report case of sore eyes to physician. Should one or both of the lids of either or of both eyes of an infant become red or swollen, or should there be any discharge from either or from both eyes, at any time within three weeks after its birth, it shall be the duty of the midwife, nurse or other person having charge of said infant at once, unless for good cause shown, to report the condition of said eyes to a legally qualified practitioner of medicine (Laws, 1895, p. 153).

Section 7531.—Health officer to furnish copy of law to midwife—secretary of state to print same. Every health officer shall furnish a copy of this article to each and every person who is known to him to act as midwife or nurse in the city or town for which such health officer is appointed, and the secretary of state shall cause a sufficient number of copies of this article to be printed, and shall supply the same to such health officers on application (Laws, 1895).

Section 7532.—Violation of the law a misdemeanor-punishment. Any failure to comply with the provisions of this article shall be a misdemeanor, and shall be punishable by a fine of not less than ten or not more than one hundred dollars, or by imprisonment not to exceed six months, or by both such fine and imprisonment (Laws, 1895, p. 153).

Missouri now has an act to provide for the immediate registration of all births and deaths under the supervision of the state board of health, and is in a position to have this law enforced.

NEBRASKA

Ophthalmologist, Harold Gifford; Obstetrician, W. C. Henry; Sanitarian, W. T. Johnson.

Dr. H. Gifford: About seventeen years ago I had a bill introduced into the Nebraska legislature placing ophthalmia neonatorum on the contagious disease list, and making it obligatory for midwives to report all cases to the nearest board of health, which was then to be instructed to advise parents of the danger of the disease and of the necessity of medical treatment. This bill, although recommended unanimously by the state society, was killed in the committee of the state legislature. Since then nothing has been done, although I propose to bring up a similar bill at the next meeting of the state legislature.

NEVADA

Obstetrician, S. K. Morrison.

Dr. S. K. Morrison writes: While the state association or its county branches have done nothing in an official way toward the enactment of laws, nor any other actions as a body, I personally have communicated with every doctor practicing in the state of Nevada, I could reach, asking them the number of cases they have had of ophthalmia neonatorum, the routine practice concerning the care of the eyes of the new-born and results of cases they have had, and I find that there were but five cases reported to me in the whole state of Nevada for the last twenty years, and only one of these resulted in complete blindness. The majority of the men are using an instillation of silver nitrate solution immediately after birth, the balance are using boric acid and silver nitrate wherever there is any suspicion that the mother is infected.

NEW HAMPSHIRE

Ophthalmologist, C. B. Hammond; Obstetrician, W. B. Garland; Sanitarian, Irving A. Watson.

Dr. Charles Hammond: During the last session of the New Hampshire legislature, there was a bill regulating the treatment of the eyes of the new-born, presented to it asking for its enactment, but it was turned down. There never has been a law on this subject, and no papers have been read in any organization of any kind relative to it. We are to try organization another year and hope for better results. There have been so few cases of ophthalmia neonatorum throughout the state that the physicians are a little apathetic regarding it. The only suggestion I have to make is to "Stick to the work if it takes years" to do it. We are on the right road, I am convinced.

NEW JERSEY

Ophthalmologist, C. J. Kipp; Obstetrician, Charles L. Ill; Sanitarian, B. S. Keator.

At the annual meeting of the Medical Society of New Jersey, held at Cape May, N. J., June 23, 1909, Dr. Charles J. Kipp introduced the following resolution:

Resolved, That this society appoint a committee which shall put itself in communication with the state board of health and with each component society to adopt a method to put a stop to ophthalmia neonatorum.

That it be recommended that the state shall make a sufficient appropriation to the state board of health to put the necessary enactments into force and to prosecute their violation.

That the new law now existing with regard to reporting cases of this disease, be so amended as to make it enforceable.

That ophthalmia neonatorum be placed on the list of communicable diseases by the state board of health and by all local boards of health.

That a law be passed compelling midwives to use such prophylactics as may be recommended by the state board of health.

A motion was made, seconded and carried that the resolution be referred to a committee to put the matter in shape for action by the society.

At the same meeting a paper on the prevention and treatment of ophthalmia neonatorum was read by Dr. T. R. Paganelli, of Hoboken, N. J.

With a view of bringing this subject again to the attention of the members of this society, the Committee on Prize Essays has selected as the subject of the essay, "The Causation, Prevention and Treatment of Ophthalmia Neonatorum, with Special Reference to Methods of Prevention Applicable in Private Practice." To the best essay will be awarded the prize of one hundred dollars, to the second a gold medal, of the value of fifty dollars.

The committee on ophthalmia neonatorum, with the aid of the attorney general of the state, has prepared an amendment to the law of 1895, an act for the prevention of blindness in the state of New Jersey, of which a copy is enclosed. We have no reason to doubt that the amendment will be passed. As soon as this is done the state board of health will distribute to all known practitioners of medicine and midwives, a copy of the law as amended, together with circular containing directions as to approved methods of prevention and treatment of ophthalmia.

A supplement to an act entitled "An act to regulate the practice of midwifery in the state of New Jersey" has been introduced in the legislature and will probably be passed.

In the hospitals with maternity wards where Credé's method is used, no cases of ophthalmia developed in the children born there during the year.

In the Newark Charitable Eye and Ear Infirmary, the average percentage of cases of ophthalmia neonatorum during the twenty-four years was 0.8 per cent. of all eye diseases. During the last four years it has been a little above 0.35 per cent. Most of the cases were in children born with the assistance of midwives. We rarely see a case in general practice.

For the substance of the law of 1895 see the report of the committee for last year.

NEW YORK

Ophthalmologist, Charles S. Bull; Obstetrician, H. J. Bolt; Sanitarian, Eugene H. Porter.

In his report to the Governor, Dr. Eugene H. Porter states: This (ophthalmia neonatorum) has been placed in the list of diseases of which Health Officers are required to make report; forty cases have been reported, no report on it from New York City being included.

This is the first entire year of work in this direction. It has been taken up for the purpose of saving new-born children from a disease which is almost certain to result in blindness. The disease is not common; it is infrequent enough to occur but few times or possibly not at all in the experience of the average physician. A suitable prophylactic applied to the eyes at birth will prevent its development. Securing its report is only a step towards effecting its control. The chief work on it this year by the department has been to induce physicians and midwives to habitually and uniformly use preventive measures on the eyes of every new-born child with which they have to do. Pledge cards to do this have during the year been sent to every practicing physician in the state outside of New York city, and every midwife whose name could be secured. Return postals to this end have been sent to 6,353 physicians and to 157 midwives: 3,702 of the former and 56 of the latter have thus far signed this pledge. This work has received general commendation from the medical profession in whatever comment is made in connection with the return of the pledge cards.

There has also been placed on the certificates of birth a question as to whether ophthalmia prophylaxis has been used in the eyes of the child whose birth is reported. The purpose of this is to keep constantly before the obstetrician this measure. Physicians will not misinterpret this as an official demand or as an interference with individual judgment as to treatment, when they reflect on the importance of the uniform and routine use of the procedure which will prevent a grave disease. During the year a prophylactic outfit consisting of a solution of nitrate of silver with apparatus and directions for its use has been prepared and a large number sent to health officers for ratuitous distribution to every obstetrician.

NORTH CAROLINA

Ophthalmologist, H. H. Briggs; Obstetrician, J. F. Highsmith; Sanitarian, George G. Thoma.

Dr. R. H. Lewis reports that nothing has been done during the last legislature. Dr. Rankin, the new secretary of the board has promised his support during the next legislature. He is in favor of trying the New York plan of getting the physicians to sign a pledge to use Credé's method in all cases.

NORTH DAKOTA

Ophthalmologist, Henry Beaudoux; Obstetrician, F. J. Campbell; Sanitarian, J. Grassick.

J. Grassick reports: No laws have been passed during the year of 1909 bearing on ophthalmia neonatorum. We have been doing education work which should count for something.

OHIO

Ophthalmologist, Mark D. Stevenson; Obstetrician, C. L. Bonnifield; Sanitarian, C. O. Probst.

Early in the present year, an extensive campaign for the education of the people for the *propaganda* in the interest of prevention of blindness was carried on under the direction of the Ohio State Commission for the Blind. Mr. M. C. C. F. Campbell, of Boston, spent six weeks in going from town to town delivering lectures with lantern slides and other illustrations. An enormous amount of literature was distributed. It was estimated that 17,000 columns on this subject appeared in the various local papers. Much important statistical work has been done by the commission.

OKLAHOMA

Ophthalmologist, J. E. Fowler; Sanitarian, B. F. Hamilton.
No report.

OREGON

Ophthalmologist, J. F. Dickson; Obstetrician, W. E. Lewis.

Dr. J. F. Dickson reports: There is not much to report except in preliminary work. Papers have been read before the State and County societies, the actions of the American Medical Association heartily endorsed, and at the last meeting of our State Board of Health, held on the 25th, ophthalmia neonatorum was placed on the list of diseases to be reported and a bulletin containing full directions for treatment, etc. (similar to that issued by the New Board) is to be sent to every physician and midwife in the state. The State Board of Health bulletin, which will be issued about the end of April, will also contain a chapter on the diagnosis, prophylaxis and treatment of this disease. Our State Medical Society meets next June, at which time definite plans will be made and a committee appointed to draft, or adopt, a suitable law covering all the points urged by your committee, and, with the aid of the City and County Medical Societies, a determined effort will be made to have it passed at our next legislature, which meets in January, 1911.

PENNSYLVANIA

Ophthalmologist, G. E. deSchweinitz; Obstetrician, Joseph Price; Sanitarian, Samuel G. Dixon.

Dr. Samuel G. Dixon: The Department of Health of this commonwealth has not been able to compile statistics on the prevalence of ophthalmia neonatorum, for the reason that the only law on our statute books referring to this disease requires that a report be made to medical men. This department did have copies of the Act, together with a circular letter, mailed to every physician in the commonwealth about one year ago. Copies with suitable letters were sent to all of the Department of Health Officers in the field, to the secretaries of the Boards of Health in all cities, towns and boroughs, and to every practicing midwife. No one connected with the department has published any papers on the subject but I did give wide newspaper publicity to the necessity for making reports at the time copies of the Act were distributed. This department is in full sympathy with the work and will be glad to co-operate with you in advancing the work.

RHODE ISLAND

Ophthalmologist, C. W. Van Benschoten; Obstetrician, D. F. Gray; Sanitarian, A. C. Sprague.

Dr. Gardner T. Swarts: As chairman of the Committee on Ophthalmia Neonatorum, I have to report to the Conference of State and Provincial Boards of Health of North America at its next meeting in Washington, April 28. I am receiving inquiries from the different state, either boards of health or ophthalmological societies, in reference to the nitrate of silver outfit. The supply which we sent out last year was fully appreciated by the physicians and we are sending out another supply this year. As the result of reading a very exhaustive report made by the Ophthalmological Society of the District of Columbia, I am looking up the question of utilizing sophol in place of the nitrate of silver. New York has sent out about 25,000 of the outfits, and Dr. Porter informs me that they had forty cases in 1909. I am about to write to the various secretaries of boards of health to ascertain which, if any others, have taken the matter up and how far they have gone.

SOUTH CAROLINA

Ophthalmologist, E. D. Parker; Obstetrician, E. S. Cathcart; Sanitarian, T. Grange Simon.

Dr. Kollock reports that in the latter part of the nineties, he presented the necessity of securing legislation for the prevention of the increase of blindness before the South Carolina Medical Association and finally succeeded in getting a law which was better than none. The law only applies to towns and cities of 1,000 inhabitants and over and the punishment for not reporting such cases was only a fine of twenty dollars or imprisonment for one month, or both. Dr. Kollock has devoted much time to this subject in his lecture to nurses of the Roper Hospital.

SOUTH DAKOTA

Ophthalmologist, E. O. Miller; Sanitarian, H. A. Peabody.
No report.

TENNESSEE

Ophthalmologist, G. C. Savage; Obstetrician, R. E. Fort; Sanitarian, J. A. Albright.

Dr. G. C. Savage: From time to time during the past quarter of a century the profession of our state have heard much of ophthalmia neonatorum and how to manage it. We have, up to the present, no law on our statute books touching this disease, and our legislature will not meet again until January, 1911.

TEXAS

Ophthalmologist, J. C. McReynolds; Obstetrician, C. E. Cantrell; Sanitarian, William Brumby.

C. E. Cantrell: A paper was read at the last meeting of the State Association at which it was suggested that a paper be read at the open meeting which is held annually in the county societies. This suggestion was adopted. From the Rules and Regulations of the Texas State Board of Health and made operative Feb. 1, 1910. Rule 22, "Nurses and Midwives shall report redness of eyelids or inflammation to Health Officer. Whenever any nurse, midwife or other person not a legally qualified practitioner of medicine shall notice inflammation of the eyes or redness of the lids in a new-born child under his or her care, it shall be the duty of such person to report the same to the local health authority, or in the absence, any reputable physician, within twelve hours of the time the disease is first noticed.

UTAH

Ophthalmologist, Fred Stauffer; Obstetrician, F. S. Bascom; Sanitarian, F. S. Bascom.

No new laws have been enacted during the past year regarding the prevention of blindness from ophthalmia neonatorum. No papers have been read before the medical societies or other organizations with reference to this subject. It is reported that there ophthalmia neonatorum is rare. There are some old laws on the statute books of the state which require a prevention treatment (Credé's method) and any physician not taking the precaution is rendered liable.

VERMONT

Ophthalmologist, F. J. Arnold; Obstetrician, C. W. Bartlett.

Charles S. Caverly: Nothing has been accomplished in this state during the past year toward the prevention of ophthalmia neonatorum and no papers have been read before any medical or popular organizations on this subject.

VIRGINIA

Ophthalmologist, J. A. White; Obstetrician, R. C. Kight; Sanitarian, R. W. Martin.

Joseph A. White: Nothing has been done in Virginia in regard to ophthalmia neonatorum. No papers that I am aware of have been read before the medical association, or any popular organizations. No laws in reference to the matter have been enacted. I have tried to interest our Board of Health in the matter, but so far without success, and it is a difficult matter to interest any of our legislature in laws regarding the public health, as there are no politics in it.

WASHINGTON

Ophthalmologist, David deBeck; Obstetrician, William H. Hall; Sanitarian, J. M. Semple.

Eugene R. Keeley: This state has no laws on the subject. I do not believe that any papers have been read on this subject before any of the medical societies.

WEST VIRGINIA

Ophthalmologist, T. W. Moore; Obstetrician, J. Cannady; Sanitarian, J. E. Robins.

No report.

WISCONSIN

Ophthalmologist, Nelson M. Black; Obstetrician, C. H. Mason; Sanitarian, C. A. Harper.

L. W. Hutchcroft: At the 1909 session of the legislature, this board succeeded in having enacted into law a provision very similar to the uniform law recommended by the association. This law together with instructions for the proper treatment of the disease, is printed in the "Powers and Duties," issued by our board and is also given on the covers of all birth booklets which are distributed to physicians, midwives and others persons required to report births.

WYOMING

Sanitarian, Fred Horton.

No report.

CONCLUSIONS

In a paper published in THE JOURNAL of the American Medical Association just prior to the meeting of 1906 and which resulted in the appointment of the committee on ophthalmia neonatorum, it was urged that the perfect organization of the physicians of the country in this great national body through its state and county constituents would make it possible and practicable to carry into effect a reform movement like the prevention of the unnecessary blindness of babies.

By the adoption of some uniform method of procedure which could be taken up in each of the states and in these through the district and county organizations, it would be possible in a comparatively short time to reach the ultimate unit and the entire profession acting together would exercise an influence that would be irresistible. Such a movement in a less coherent organization would be impossible and the exceedingly gratifying results which have so far been obtained have been due to the cordial effective and untiring support which has been given to the efforts of the central committee from one end of the nation to the other.

It became evident as the work opened up that a relatively uniform method of procedure was essential to success. Most physicians do not need to be told what to do to prevent or cure a gonococcic birth infection, but because of the infrequency of these cases in the daily work of the average general practitioner and the disastrous consequences which follow the neglect of early treatment, the danger in the occasional case is overlooked in a great number of cases and the aggregated blindness is, therefore, by no means inconsiderable. The only way in which the careless or indifferent individual can be reached is by making general the adoption of a plan which with him, as with others, will become a routine method of procedure. In some instances, a seeming indifference has been shown because of the expressed belief that in that particular section of the world, ophthalmia neonatorum is non-existent. In almost every such instance, further investigation has shown that the cases simply had not been brought to public notice. One exceedingly efficient health officer wrote that the disease was practically unknown in his little state, but a subsequent letter reported that he had found four cases in his own town. He has become a most enthusiastic propagandist for prophylaxis. Gonococcic birth infections occur wherever gonorrhea is found and this disease, alas, is ubiquitous.

If we would wipe out this pestilence, it can only be done through the coordinated efforts of the organized medical profession. So your committee urges once more and with added emphasis, its recommendations of one year ago: Make renewed efforts through the state and county societies to have births reported to the health officer promptly; secure adequate midwife laws or give such improved obstetric teaching as will drive the midwife out of business, as has practically been done in Boston; ask on every birth certificate, whether or not a prophylactic has been used, and if not, why not—not as has already been shown by the New York State Board of Health in its monthly Bulletin, as an infringement of personal liberty (for every obstetrician may of course do as he will)—but as a reminder, to the indifferent and careless, of the necessity of protecting the babe from possible disaster almost worse than death. Distribute the chosen and inexpensive prophylactic through the state Department of Health generously and gratuitously. Every time the accoucheur sees the little package with its warning literature, it is an impressive object lesson and if one child is thereby saved from blindness, it is worth more than the cost of the distribution of the preparation throughout an entire state. Secure in the cities adequate provision in the hospitals for children in whom infective inflammation has occurred; special nurses for continuous day and night duty are expensive and increase the *per capita* cost of maintenance. They are not always provided for pauper babies, but there is no hospital management so devoid of human feeling as to permit even a beggar's child to become blind when the danger is pointed out. Moreover, a blind person saddled for life on a community is an expensive luxury. Prophylaxis and early treatment are prudent economic measures on the part of any commonwealth.

It early became apparent to your committee that any preventive propaganda to be successful must have the support of the general public. When the patient reaches the physician, the disease is an accomplished fact. In order that it may be anticipated and prevented, measures must be initiated and carried into effect by the people themselves. Our efforts for the prevention of tuberculosis never gave any hope of success until they took the form of a popular movement. Your committee was exceedingly fortunate, therefore, as already reported, in securing the cooperation of the committee on prevention of the New York Association for the Blind with the most generous financial support of the Russell Sage Foundation. Six valuable publications have been issued by this latter organization for general gratuitous distribution. An extensive practical exhibit on ophthalmia neonatorum with stereopticon slides and the skeleton of a lecture has been provided and will be loaned to our committees for demonstrations before state or other societies, or for popular lectures on any occasion when not otherwise in use. Associations have also been formed in others of the states, and in several of them commissions for the blind, that of Massachusetts having an annual appropriation of forty thousand dollars, and each is making the prevention of blindness one of its chief ends and reasons for being.

It became apparent with this multiplication of agencies working along similar lines and with like ends in view that there would soon be an overlapping of effort and waste of energy unless all of this work could in some way be coordinated. This possibility was emphasized by a letter which came in January last to Miss Louisa Lee Schuyler, chairman of the committee on prevention, and also a member of the Sage Foundation Trust, the woman to whom the success of this movement is largely due. Actively occupied as she is in the wise direction of a number of important charities, she still finds time for personal service in this one, the prevention of unnecessary blindness. This letter came from Mr. James P. Monroe, chairman of the Massachusetts Commission for the Blind. A portion of it reads as follows:

> "In view of the fact that this work is still in the experimental stage, that there is possible danger of its taking wrong directions, and that there is certain danger of unnecessary duplication of effort, it would seem to me very desirable to hold, at a comparatively early date, an informal conference, to which should be invited representatives from New York, Massachusetts, Ohio, Pennsylvania, Maryland, New Jersey and perhaps one or two other states. Such a round table conference would help, generously supported by the Sage Foundation, along lines that would be most effective and least liable to needless duplication. We fear, unless this movement for

prevention is kept in the controlling hands of those who have had experience, there is danger that it may be carried forward in an unwise way by amateurs."

The conference suggested was held in New York on February 16, and all of the states mentioned were represented except New Jersey. The presiding officer was Mr. John N. Glenn, director of the Russell Sage Foundation. A simple form of organization was effected and a committee appointed with authority to call other meetings as occasion might require.

The general sentiment expressed by representatives from all of the states was that success in the prevention of blindness was contingent on one word, cooperation, and the representatives from each of these states gave their hearty assurances of willingness to aid in a general movement on these lines.

It will be readily seen that the rapid development of this movement with its important lay associations soon made it evident that it could not be adequately managed by any ordinary medical committee. The effective work accomplished in one state may be utilized with great advantage in another; medical and lay committees can be brought together and a plan of campaign determined on. The literature used in one state can often serve as a basis for like publications in another. But such work to be successful would require the entire time of a capable trained man. Our necessities were, therefore, again presented with the certainty of a sympathetic hearing to the trustees of the Russell Sage Foundation and again an appropriation was made which made the appointment of such a man possible. The trustees have chosen for this work, Mr. Samuel E. Eliot, a graduate of Oxford and Columbia universities, a man especially endorsed and excellently trained for this important work. His services are offered to our committees wherever they may with advantage be employed.

So general and widespread has this movement become and so ready has been the recognition of the need of cooperation that the prevention of blindness has been chosen as one of the topics to be considered at the National Conference of Charities and Corrections to be held in this same city (St. Louis) in May, under the able chairmanship of Dr. Charles Emerson, now of Clifton Springs, formerly of Johns Hopkins University, Baltimore, and whose work in hospital social service in that city is so well and widely known. The paper will be read by Miss Carolyn C. Van Blarcom, the able secretary of the committee on prevention of the New York Association for the Blind. The theme will again be coordinated work and the appointment of a committee from this great organization will be requested.

Still further, with the broadening of the subject, the necessity of the interest and the influence of the educators of the country is evident. To lay the foundation for the development of this greater preventive work an address will be delivered before the National Educational Association at the meeting in Boston in July, on the Conservation of Vision and the Prevention of Blindness, and the aid of a special committee will be invited from that organization.

One of the most efficient agencies for the promulgation of this propaganda has been the Federation of Woman's Clubs and the Public Health Education Committee of this Association. This again affords an organization so complete that the entire country may be effectively and quickly covered.

It is evident from the foregoing that just now the conditions of time and circumstance present extraordinary opportunities for preventive work on ophthalmic lines with an all but universal readiness to aid in this movement. To be successful, however, it is essential that it be guided and directed by medical men.

The committee on ophthalmia neonatorum in each state makes an excellent nucleus for the development of this larger work which might be augmented by committees from the National Association of Charities and Corrections, the National Educational Association, the Committee on Public Education of this Association, the Confederation of Woman's Clubs and other allied organizations. These could accomplish ends which for any one of them alone would be impossible.

Your committee therefore recommends that this work be continued with its scope broadened and enlarged to comprehend in its largest sense the prevention of blindness.

Most respectfully submitted.

F. Park Lewis, Chairman.
J. Clifton Edgar.
F. F. Wesbrook.

On motion, the report was adopted and the committee continued.

The Chairman stated that he would be glad to consider a motion to limit the time of the reading of the reports.

Dr. C. R. Woodson, Missouri, moved that the reports be read by title or not exceed five minutes.

Seconded.

Dr. C. E. Cantrell, Texas, said 5 minutes is not sufficient time for making such reports.

Dr. Alexander R. Craig, Pennsylvania, moved to amend that the time limit be 10 minutes.

The amendment was seconded, accepted, and the original motion as amended was carried.

Dr. Henry O. Marcy, Massachusetts, Chairman, presented the report of the Committee on Davis Memorial.

On motion of Dr. A. P. McCormack, Kentucky, the report was referred to the Board of Trustees.

The report of the Committee on Nomenclature and Classification of Diseases, Dr. Frank P. Foster, New York, Chairman, was called for, and in the absence of Dr. Foster, Dr. Alexander R. Craig, Pennsylvania, moved that the report be read by title and referred to the Reference Committee on Miscellaneous Business.

In the absence of Dr. Walter B. Cannon, Massachusetts, Chairman, the report of the Council on Defense of Medical Research, on motion of Dr. A. P. McCormack, was referred to the Reference Committee on Legislation and Political Action.

Dr. Charles S. Bacon, Illinois, Chairman, read the report of the Committee on Patents and Trademarks.

Dr. Alexander R. Craig, Pennsylvania, moved the adoption of the report with its recommendations, and that the committee be discharged.

Seconded.

The report was discussed by Dr. C. S. N. Hallberg, Illinois, who moved that the report be referred back to the same committee for the purpose of considering the question of aspirin, to which reference was not made in the report of the committee.

Seconded.

Dr. E. J. Goodwin, Missouri, moved as a substitute that the report be referred to the Reference Committee on Legislation and Political Action.

Seconded.

The motions of Drs. Hallberg and Craig having been withdrawn, the President put the motion of Dr. Goodwin, which was carried, and the report was so referred.

Dr. Thomas McDavitt, Minnesota, Chairman, read the report of the Committee on Uniform Regulation of Membership.

It was moved and seconded that the report be referred to the Reference Committee on Amendments to the Constitution and By-laws.

Dr. W. H. Sanders, Alabama, stated that for a long time he has entertained and maintained some definite views with regard to the thorough and radical reconstruction of the Constitution of this Association, and not seeing any prospects of carrying out those views by participating in the work of this committee, he declined to serve on it, and now asked that his name be stricken from the committee. He has always believed that this Association ought to be an association of state organizations and not an association of individual physicians of the different states, and therefore if it is an association of state organizations, it should have no control over the affairs of county medical societies; that these matters should belong entirely to the state.

Dr. Alexander R. Craig, Pennsylvania, moved that Dr. Sanders be permitted to withdraw his name from the report of the committee.

This motion was seconded and carried, and the report of the committee was then referred to the Reference Committee on Amendments to the Constitution and By-Laws.

In reference to the report of the Committee on Elaboration of Principles of Ethics, the General Secretary read the following letter from the Chairman of this committee, Dr. Frederick C. Shattuck, Massachusetts:

Boston, Jan. 13, 1910.

Dr. George H. Simmons.

Dear Doctor:—After prelimin [illegible] and some interchange of views, the Committe[illegible] of the Principles of Ethics of the American [illegible] met in Atlantic City, June 9, 1909.

After full discussion, it was unanimously voted that it is not expedient to take any action at present. The Principles of Ethics are fairly well set forth by the Society now. This country is so large, and custom, as well as the conditions of life, vary so widely with the character of the communities, states and groups of states which comprise the country, that the committee believe it to be an impossible task for the American Medical Association to cover the whole ground and provide for anything like the variety of questions which arise and are bound to arise. The Association sets forth the general principles of ethics, and it seems to your committee far better to allow the individual state societies to provide for details in such way and as far as they may deem wise.

On motion of Dr. Edward Jackson, Colorado, the report was received and the committee discharged.

The report of the Committee on Revision of Pharmacopeia, Dr. Reid Hunt, District of Columbia, Chairman, was, on motion, referred to the Reference Committee on Miscellaneous Business without being read.

The report of the Committee on Anesthesia was read by the Chairman, Dr. James G. Mumford, Massachusetts.

Report of the Committee on Anesthesia

To the Members of the House of Delegates of the American Medical Association:

Your Committee on Anesthesia has the honor to submit the following report of progress:

This committee, appointed at the annual session in June, 1909, is properly the successor of the Anesthesia Commission of the Surgical Section, a Commission which existed during the years 1907, 1908 and 1909, and has now ceased its functions.

The present Committee on Anesthesia met in New York for organization on Oct. 29, 1909. Dr. J. G. Mumford of Boston, was elected chairman; Dr. Alexander Lambert of New York, vice-chairman, and Dr. H. A. Fowler of Washington, secretary.

Inasmuch as the committee had received no instructions from the Association regarding its purpose or method, the committee thought best to pursue its work somewhat after the fashion of the previously existing Commission of the Surgical Section. Accordingly, it has followed certain lines of research on anesthesia and anesthetics, devoting itself especially to four topics.

1. Research on the best anesthetic to use under varying morbid conditions.
2. Further investigation on the value of the various ethyl compounds as anesthetics.
3. Further investigation on the value of nitrous oxid as an anesthetic.
4. An investigation of the use of anesthetics in traumatic surgery, including military surgery.

Your committee met again on March 20, 1910, in New York, and again on June 6, 1910, in St. Louis. It reports in general terms progress, though it finds itself unable as yet to submit full and final reports for publication.

1. The research on the best anesthetic to use under varying morbid conditions has been confided to the direction of Dr. George W. Crile, of Cleveland, who, with his associates, has kindly consented to pursue the investigation, and has already made gratifying progress, some of which has been reported in current medical journals. Dr. Crile's work has been largely on the use of nitrous oxid, combined or not combined with morphin and scopolamin.

This investigator now informs the committee that he has employed nitrous oxid, combined with oxygen, in 1130 cases; that of these cases 1000 represent major operations; of these 1,000, 139 had nausea (9 severe nausea, and 4 of the 9 nausea lasting two or three days); in all the other 861 cases there was practically no nausea. When scopolamin and morphin were employed before the nitrous oxid and oxygen (759 cases) there was often a slight feeling of nausea during the recovery, and sometimes immediate vomiting.

Dr. Crile employed these forms of anesthetics (nitrous oxid and oxygen, with or without scopolamin and morphin) in his general routine work, and was satisfied that in the hands of highly skilled anesthetists the method is the best yet devised. This statement of Dr. Crile's is a supplement to a statement made by him in the *Southern Medical Journal* for January, 1910, in which he discusses the effects of ether on the vital forces and concludes (a) that it contributes to postanesthetic depression and (b) that it impairs immunity. These matters will be treated by the committee at length in its completed report, to be published later.

In connection with the subject of ether and immunity your committee will publish a paper also by Dr. Evarts A. Graham, of Chicago, whose important contribution reaches the committee through the courtesy of that investigator.

2. Further investigation on the value of the various ethyl compounds as anesthetics strengthens the conviction that these compounds are associated with a relatively high death rate; while the compounds themselves are not serviceable for prolonged anesthesia.

3. Further conclusions on the value of nitrous oxid as an anesthetic are summed up in a paper prepared by Dr. W. D. Haggard. His conclusions are essentially those already enumerated in Dr. Crile's contribution, the upshot of the investigation being that as a routine anesthetic nitrous oxid has a peculiar value, but that it must always and inevitably be administered by a highly trained specialist in anesthesia. Your committee cannot too strongly deprecate the routine use of nitrous oxid by general practitioners.

4. The committee has planned an extensive investigation of the uses of various anesthetics in military and traumatic surgery. This investigation is in the hands of Dr. H. A. Fowler, of Washington, who is assisted by Col. LaGarde, of the army, by Dr. Robert T. Miller, of Pittsburg, and by Dr. Gaston Torrance, of Birmingham, Ala. The committee thinks it unlikely that a satisfactory statement of the matters under this heading can be made before one, and possibly two, years to come.

In concluding this extremely brief statement of progress, the committee insists again on the wide distinction between anesthetics proper for use by general practitioners and anesthetics which may be employed by experts. As time goes on and wider knowledge accumulates, your committee feels more and more convinced that the distinction between these two classes of anesthetists is vital, and it repeats the statement in the report of the Commission on Anesthesia for the Surgical Section in 1908:

> 1. "That for the general practitioner, and for all anesthetists not specially skilled, ether must be the anesthetic of choice—ether administered by the open or the drop method.
>
> 2. "That the use of chloroform, particularly for the operations of minor surgery, be discouraged, unless it be given by an expert."

And your committee now adds the further recommendation, as already stated, that the use of nitrous oxid, whether combined with air or oxygen, and whether or not preceded by scopolamin and morphin, be confided invariably to the care of an expert.

J. G. MUMFORD, Chairman.
ALEXANDER LAMBERT.
W. D. HAGGARD.
H. A. FOWLER.
H. C. WOOD, JR.

On motion of Dr. Alexander R. Craig, Pennsylvania, the report was accepted, the committee continued, and referred to the Reference Committee on Miscellaneous Business.

Major M. W. Ireland, U. S. A., Chairman, read the report of the Committee on Selection of Insignia for A. M. A.

On motion, the report was referred to the Reference Committee on Miscellaneous Business.

Dr. Edward Jackson, Colorado, Chairman, presented the report of the Committee on Establishment of Physicians' Sanitarium.

Dr. A. T. McCormack, Kentucky, moved that, inasmuch as this report involves the appropriation of money, it be referred to the Board of Trustees.

The General Secretary read the report of the Committee on Monument to Civil War Surgeons.

Report of the Committee on Memorial to Medical Officers Who Died in the Civil War

To the Members of the House of Delegates of the American Medical Association:

By reference to the official minutes of the sixtieth annual session held at Atlantic City, N. J. (THE JOURNAL, June 19, 1909, p. 2077), it will be observed that the house adopted the favorable report of the Reference Committee on Reports of Officers in reference to the erection, in the national capital, of a memorial to the medical officers who gave up their lives during the Civil War.

Of the central committee of five authorized by the House of Delegates to be appointed by the president at that time, Drs. S. Weir Mitchell of Philadelphia, and G. Lane Taneyhill of Baltimore, have accepted appointment. These members, desiring to have a representative from the medical corps of the regular army on said committee, insisted on the appointment, by himself, of Col. William C. Gorgas as a suitable member. It has also been suggested that the two remaining positions be filled by the appointment of an available volunteer surgeon of the Union Army and a similar one from the Confederate Army. This step is now in progress of being consummated. By this method the central committee of five will be the better enabled to complete the general committee of one from each state, etc., as authorized by the House of Delegates.

Your committee confidently believes that the meritoriousness of the object contemplated strongly appeals to the sense of justice of this intelligent House, especially when we consider that it is "to commemorate men who fell in the service of *our* common humanity and who belonged to that great guild which no war can tear asunder."

Your committee respectfully recommends that it be continued, with the same privileges, instructions and appropriation authorized by the House at the Atlantic City meeting.

Respectfully submitted.

WILLIAM C. GORGAS.
S. WEIR MITCHELL.
G. LANE TANEYHILL.

On motion of Dr. Alexander R. Craig, Pennsylvania, the report was adopted with the recommendations contained therein approved, and the committee continued.

Under the head of "New Business," Dr. Alexander R. Craig presented a petition to the House of Delegates which contemplates the formation of a new section, to be known as Section on Physical Forces in Medicine, and moved that the petition be referred to the Reference Committee on Section and Section Work.

Dr. E. Carson Hay, Hot Springs, Ark., presented a petition for the creation of a new section on Urology and Venereal Diseases, saying that 130 or 140 names were appended to the petition.

Dr. Hugh Young, Maryland, moved that it be referred to the Reference Committee on Sections and Section Work.

Seconded and carried.

Dr. W. H. Sanders, Alabama, presented the following resolutions, adopted by the Medical Association of the State of Alabama at its meeting, held in Mobile, April 19-22, 1910:

WHEREAS, Efforts are now being made to provide by Congressional enactment for the establishment of a National Public Health Organization; therefore, be it

1. *Resolved*, By the Medical Association of the State of Alabama, that in providing for such an organization, it is the sense of this body that the principles of the Constitution involving the exercise of the police power, as announced in a long line of decisions of the Supreme Court of the United States, should be rigidly adhered to.

2. That any organization for the exercise of Public Health Functions that may be established should be widely and effectually divorced from politics, to the end that all persons who may occupy official positions therein should be selected on the basis of their qualifications as sanitarians and their administrative ability, and not on party affiliation.

3. That the proposed organization should sustain some direct and organic relation to the medical profession of the several states as organized and chartered for public health purposes.

4. That a copy of these resolutions be transmitted to the Senators and Representatives in Congress from this state, and to the American Medical Association at its next meeting.

The President stated that unless there was some objection, these resolutions would be referred to the Reference Committee on Legislation and Political Action, and as there was none, the resolutions were so referred.

Dr. Sanders also presented another set of resolutions which were adopted by the Medical Association of the State of Alabama at its meeting, held in Mobile, April 19-22, 1910:

WHEREAS, A committee was appointed at the last meeting of the American Medical Association to reconstruct and rewrite the Constitution and by-laws of that body, and to investigate and report on other matters connected with the organization of said body; and

WHEREAS, It is expected that said committee will report the results of its work at the forthcoming meeting of the American Medical Association; therefore, be it

Resolved, By the Medical Association of the State of Alabama, that the delegates of this Association to the next meeting of the American Medical Association be, and they are hereby, instructed to insist on the incorporation into any new constitution that may be adopted by the American Medical Association of the following principles:

1. That the fundamental and important principles of organization be embodied in the constitution, and that the principles of secondary importance and the details of organization be embodied in the by-laws, the reverse being largely the rule in the present constitution and by-laws of the American Medical Association.

2. That in providing for the offices of the Association, the principles should be laid down that no person should at the same time fill two official positions.

3. That a charter for the American Medical Association be obtained from the United States Government, should it be acertained that the right to grant such a charter resides in the Congress of the United States.

4. That whether a charter for the American Medical Association be obtained from the United States Government, or from a state government, it should incorporate the American Medical Association as a body and not the Trustees thereof, as is the case under the existing charter.

On motion, these resolutions were referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Dr. Samuel Wolfe, Pennsylvania, presented the following resolutions:

Resolved, That the House of Delegates hereby specially endorses and approves the statistical and editorial work of THE JOURNAL of the American Medical Association in reference to the fatalities and casualties resulting from the present methods of celebrating the Fourth of July, now carried on over a period of more than seven years, and recognizes in it the main factor in the crystallization of sentiment and the chief incentive to the activity so apparent within the last few years.

Resolved, further, That we urge the continued and additional cooperation in this important field of the newspaper and magazine press of the country, of all municipalities, of civic, religious and [illegible] of all public-spirited men and women, and [illegible] nized way of all state and county medical societies.

On motion, the resolutions were referred to the Reference Committee on Hygiene and Public Health.

Dr. Joseph A. Capps, Illinois, presented the following resolution, which was referred to the Reference Committee on Sections and Section Work:

WHEREAS, By reason of the vast strides that are being made in Pathology, Bacteriology, Urinology, Serum and Vaccine Therapy, and the development of the various scientific aids to diagnosis, and because the facilities for making use of these many agencies in the cure of disease are costly and complicated; and further, because they demand skill and education of a highly technical order for their successful use, hospitals in which these scientific instruments can be concentrated and employed are becoming more and more a necessity for the treatment of the poor, but for every class of society. It is not necessary in this modern day that hospitals shall nurse and feed the sick; they must at the same time take scientific care of patients under the modern practitioner's directions. To do this, it is necessary to have scientific men, specially trained, in charge of modern hospitals; and that these hospital administrators shall study the problems of the medical profession in conjunction with the practitioners whom they must aid. Recognizing these necessities, the House of Delegates of the American Medical Association therefore

Resolved, That there is hereby created a section of the Association to be known as the hospital section.

Dr. Luther M. Halsey, New Jersey, stated that at the last session of the House of Delegates of the American Medical Association, held at Atlantic City, N. J., a resolution was introduced asking that the Committee on Scientific Exhibit be published in THE JOURNAL along with the other committees. This was done at the request of Dr. Wynn. A great deal of confusion had arisen because the Committee on Scientific Exhibit was not published in THE JOURNAL, and Dr. Wynn had received many letters from different parts of the country asking the name of the chairman on Scientific Exhibit. He therefore moved that this matter be referred to the proper committee. He would suggest, further, that the whole matter of arranging for the Scientific Exhibit be placed in the hands of Dr. Wynn, with power to act, rather than be entrusted to the local committee.

The President stated that unless there was objection, this matter would be referred to the Board of Trustees, and as there was none, it was so referred.

On motion, the House of Delegates adjourned until 2 p. m. Tuesday.

(*To be continued*)

Opening General Meeting

Tuesday, June 7, 10:30 A. M.

The general opening meeting of the Sixty-First Annual Session of the American Medical Association was held at the Odeon Theater, Tuesday, June 7, 1910, at 10:30 a. m. The meeting was called to order by President William C. Gorgas, of Panama.

Prayer was offered by the Rev. Charles S. Mills, D.D., St. Louis.

Address of Welcome

The President introduced Dr. Henry Schwartz, President of the St. Louis Medical Society, who delivered the address of welcome:

Mr. President, Ladies and Gentlemen: On behalf of the St. Louis Medical Society I extend to the officers and members of the American Medical Association, to their families and to their guests, a most hearty welcome. The St. Louis Medical Society appreciates the honor you have conferred on it by convening in St. Louis. It likewise appreciates the help and the encouragement which your coming here gives to the work of the organized medical profession of this city. Your influence has already helped us in our efforts to unite all reputable practitioners in one harmonious fellowship. We expect still greater benefit from this convention because our fellow citizens will learn that the St. Louis medical profession is an integral part of the great American Medical Association. They will learn what a mighty factor that Association is in promoting the science and art of medicine, in elevating the standard of medical education, in securing and enforcing just medical laws, and in enlightening and directing public opinion in regard to the broad problems of hygiene. Such information will cause the citizens of this great commonwealth to rally around its medical profession and to assist it by every effort to do its full share of this great and patriotic work.

Your program for this convention shows what an immense amount of work will be done in the next few days, and we sincerely trust you will be able to mix your work with recreation in such a way as to live up to that part of the constitution which pledges us to promote friendly intercourse among

American physicians. We have lived in joyful expectancy of your visit, and now you are with us, every member of the St. Louis Medical Society stands ready to grasp you by both hands and shout from the bottom of his heart, welcome! welcome! welcome!

Address of Welcome on Behalf of the Medical Profession of Missouri

Dr. Herman E. Pearse, Kansas City, president of the Missouri State Medical Society, was then introduced and delivered an address of welcome:

Mr. President, Ladies and Gentlemen: We are a great and growing state here in Missouri; we have a great and growing profession, and we recognize you as the greatest and strongest body that we have in this country; we welcome you here for the good that you can do to the people that we have been working for. If you work as hard in the next five days as we have here in the last ten years, this speech of welcome will be followed by a speech of gratitude which will require a better talker than I to do it justice.

We welcome you here to-day, to help us in the battle that is being fought in the United States for the freedom of its people. We see you come with every influence in the United States that is opposed to the public health movements skulking at your heels and flanks and proclaiming its attacks in every daily paper. The "pure food law" is making unprofitable the business of every quack doctor, and every one who has fattened on the misfortunes of the poor and on the credulity of the ignorant, and we welcome you to the four or five days' battle here. In this connection I am reminded of what one of our famous generals said, who when little reenforcements came to him for duty: "Wade right in, gentlemen, you will find elegant fighting all along the line."

Address of Welcome on Behalf of the Medical Profession of St. Louis

Dr. W. G. Moore, St. Louis: *Mr. President, Ladies and Gentlemen:* I am aware that five minutes has been allowed for what we have to say. I wish it were longer for myself, but for your sake I am glad it is no longer. I realize that no pleasanter duty could have been given me than to welcome you to this city.

I believe that this Association has in its present and in its incoming President two of the greatest and most useful men within the borders of the United States. Their usefulness goes out like the sunshine on the just and the unjust. And the Governor is here honoring himself in honoring you. He is ready to extend a full and free pardon for any sins of omission or commission that may be committed within the borders of Missouri during the next four days. The Mayor is likewise here to present to you not only the key to the great outer gate, which admits you to our warmest hospitality, but also a bunch of keys which unlocks every door and admits to the treasures or pleasures under his control. I am here, gentlemen, to speak to you a word for the great militant body of the St. Louis profession—a body of men than whom you will not find more noble, efficient or loyal, the maledictions of the Carnegie articles to the contrary notwithstanding. You will find among them royal companions. You will find among them also men capable of filling the highest offices in your gift with credit to themselves and to you.

Many long years have passed since you were our guests, entirely too long for our hospitality, which fact we hope to prove to you before our deliberations come to a close. The North, East, South and West are equidistant from this convention city. I recognize before me the greatest body of men that can be gathered together in America, and I mean that as fully as I am capable of meaning anything. Judged from the standpoint of pure philanthropy and the possibilities of the greatest good to the greatest number of our fellow citizens, there comes from the city of New York the cheery information that you are a trust—the informer is one B. O. Flower, the president of the "National League for Medical Freedom" and the editor of the *Twentieth Century Magazine*. Flower has caused to be printed in our daily papers the following questions in "scare" headlines:

"Do you want government by political doctors?"

And I answer: "We do!"

"Do you want health and hygiene to be represented by an army of United States Inspectors under the direction of a Medical Bureau?"

And I answer, that this is a consummation devoutly to be wished.

He asks if we know that William H. Welch, president of the American Medical Association, told the Senate Committee on Public Health and National Quarantine, that physicians wanted such a National Department of Public Health for the purpose of influencing state and municipal boards of health, and that he felt the Constitution could be so interpreted as to give the national board the power to regulate health affairs, nationally. We did not know this, but if it is true, it affords us another opportunity to hurrah for Welch and to applaud him.

If the American Medical Association be a trust, it furnishes a part of what our political brethren have sometimes said—that there is such a thing as a good trust—a statement which I never believed before.

This is a trust concerning which we may say that about 20 or 40 per cent. of its earned increment goes to sweet charity; a trust whose every discovery or invention is for the benefit of the sufferers of our race and becomes the property of prince and pauper alike; a trust whose efforts redound to the uplift of mankind and which constantly limits its own sources of income, by diminishing the ills that flesh is heir to.

If it be a sin to decry such a trust, then I glory in the companionship of such sinners. The medical profession has never asked for a law that was not beneficent in its intent, and if it is true and loyal to its traditions, it never will. Let us differ as we may and will about different questions, when it comes to the enactment of laws for the benefit of the people, we band ourselves together and throw our whole strength on righteousness and weary not in well-doing. All hail, then, to the honorable Senator Owen of Oklahoma, who has become the advocate of the creation of a national Department of Public Health, and of a position in the Cabinet of the President, at Washington, which we should have had from the beginning of the Government. Let us see to it in the future that all positions of this character are held by medical men in municipal, state and national governments, who are fully qualified to fulfil their duties without regard for politics, and so long as they continue to discharge those duties successfully, they should not be removed for mere political expediency. It is not fair that men who are willing to devote their lives to the sick in body and mind should be treated in such a manner.

There are no strangers within our gates; not even those brave men who have journeyed to us from across the seas, to mingle their efforts with our own that the suffering of humanity may be lessened and that the world as an abiding-place may be made better.

Address by Governor Hadley

Hon. Herbert S. Hadley, Governor of Missouri: *Mr. President, Ladies and Gentlemen:* I am very glad indeed, as the chief executive of the great State of Missouri, to extend to the members of the American Medical Association a cordial welcome within the confines of this state. I not only welcome you here to our soil, but I welcome you to our splendid Italian—or Siberian—climate. It is a distinct pleasure, this morning, to be with so many learned members of the medical profession. It is so often that we lawyers have the medical profession with us, that it is a privilege for us to turn the tables, and we enjoy not only the sense of pleasure, but a sense of security on an occasion such as this, when we laymen realize that there is no danger of anybody dying without medical assistance.

I do not know whether I am in the right place, or not. The remarks of the last speaker seem to indicate that there is some question as to whether the American Medical Association is a trust, or not. I consider myself sufficiently expert on the subject of trusts, however, to say that this trust is welcome and thrice welcome within the confines of the State of Missouri. I only hope that this trust, which I here now diagnose with complete confidence, as a good one, at the able direction of its incoming president, Dr. Welch, can assist in doing for the United States of America, what the medical profession, under its outgoing President, Dr. Gorgas, with the assistance of the United States Army, has done for the Canal Zone.

I am glad to know that you members of the medical profession not only believe in something besides making money and keeping out of jail, but that you are also willing to fight for your belief; and if the other professions of this country—particularly my own—are to continue to rank among yours in respectability and public confidence, it must enjoy the distinguished pleasure of imitating your example.

I trust that the sessions and deliberations of this Association will be of benefit to the people of this state. As has been well said, there can be gathered together no body of men whose deliberations would excite more general interest than the members of this profession. Your work has to do not only with the problem of human weakness and human disease, but it has to do with the overpowering problem of human existence itself. Twice in the life of each of us we require the services of a physician, and your capacity for usefulness is not limited to the relief of human weakness and disease. Your work has not only contributed to the advancement of civilization, but it has increased the duration of life and added to the capacity of man for healthful and proper enjoyment.

Sometimes, in your efforts to make progress and to acknowledge error, doubt is aroused and suspicion raised in the minds of the layman as to the science of your profession itself; when we find one year a certain method of treatment of disease is abandoned and a radically different method adopted, the cry is apt to be raised, that, after all, the practice of medicine is but an intelligent system of empiricism, and that we are taking long chances when we summon a medical man to help us in distress. To my mind, that is one of the most hopeful indications of progress that unfortunately is not imitated by all of the learned professions. The advancement of the medical profession along scientific lines constitutes one of the great achievements and triumphs of this wonderfully progressive age.

It may be, however, that we are moving in cycles, because it is unquestionably true, that much that you do to-day has been done in the past and then has been forgotten. I find that many of the instruments with which you surgeons perform your most delicate and scientific operations have been discovered in the ruins of antiquity—indicating that these operations were unquestionably known to, and performed by, the ancients. But, however that may be, it is a far cry from the herbs and incantations of the medicine-man of the savages to the asepsis of the operating-room and the antitoxins of the scientific medical man of to-day. And the work you have accomplished along that line, although it may seem at times to cause public distrust or lack of confidence, is simply, in my judgment an indication of the feverish anxiety that you have to move faster to the consummation, which I am confident, you will eventually reach when you find an antitoxin for every disease that is known to the human system.

I have heard a story from one of the leading medical men of this country, told with anguish of spirit, as to how he lost a splendid boy from diphtheria, because physicians, although they had discovered the antitoxin of that disease, had not yet learned the science of its administration. But no one can stand by the bedside of a child, watching it clutch its mouth and throat in its fight for air, and see the wonderful effects of the administration of antitoxin against diphtheria, without taking off his hat in gratitude and respect to the scientific medical man for this wonderful contribution to the development of medical science.

Truth never seems so simple as when it has been scientifically ascertained and announced; and after many of these things you medical men discover and tell us about, we wonder that you did not discover them and tell us about them many years ago. Nobody of intelligence to-day questions the germ theory of disease, and yet that theory was scientifically ascertained and definitely announced within my own lifetime. To-day the medical profession knows accurately the habits and all the characteristics of the germ of tuberculosis. We are simply grateful to you for having done so much, and that you have taught the individual how he may substitute himself in the manufacture of vaccines from his own person and prosecute this work of segregation for himself.

But your activities as a profession, fortunately, have not been confined to these professional investigations and discoveries that have to do with the treatment of special diseases. I undertake to say that your work along the lines of preventive medicine and of movements for the improvement of the public health are, more than any others, the reasons why the medical profession holds—as it does hold to-day—its deservedly high rank in public estimation and esteem, and the work and the future usefulness and development of the medical profession, in my judgment, will lie not so much in curing or in making sick people well, as it will in preventing well people from becoming sick. Along the line of correction of those conditions which result in the impairment of public health, medical men and the public official have come in contact and the public official who is performing his duties with the sense of proper obligations has found in the medical man not only a willing, but an effective coadjutor for the accomplishment of proper results. And I undertake to say that the time is not far distant when the American people will recognize the inconsistency—if not absurdity—of spending millions of dollars each year for the protection of our cattle and our sheep and our hogs from the ravages of disease, and spending but a few paltry dollars for the protection of our women and men and children.

I am glad to welcome you to the confines of this splendid commonwealth this morning, because public sentiment of this state has been in accord with the work of the advanced and progressive members of your profession. Up to the last session of the state legislature we had only a State Board of Health, with limited powers for the accomplishment of those measures of possibility that always lie within the work of such a board. By that legislature there was enacted a law establishing in this state a Bureau of Vital Statistics and giving new powers to the State Board of Health for the accomplishment of the proper measures of usefulness.

That Bureau of Vital Statistics has been in operation for three months or more, and during that time statistics have been kept and recorded, and I am glad to say this is an indication of the effectiveness of the medical profession in a certain class of cases, namely, the births numbered 16,000, while the deaths were only a little over 12,000. So, you see, here in Missouri we are both the opponents of race suicide and believe in the principle of the "full baby-buggy."

Further than this, I have taken the position that the State Board of Health should be composed of men who are interested in one of two lines of medical work. As I have the appointment of that board, I have a right to be discriminating, and that board must be composed of physicians who have been interested either in the improvement of medical education or in the protection of the public health. I have appointed, and I intend to appoint, on that board only members who receive the endorsement or recommendation of the State Medical Association.

I do not disregard or hold in light esteem the work of those investigators and, perhaps, I might say reformers, who are undertaking to improve the conditions of our public charities and our penal and reformatory institutions, when standing before this audience of medical men; and I feel it would not be improper for me to repeat what I said, when standing before a convention composed of workers along these lines of public charities, that I have received from no department of government so much sane, practical and effective assistance in the correction of conditions in our eleemosynary and penal institutions as I have received since I have been Governor of Missouri from the inspections and recommendations of the State Board of Health. In the work of improving the Missouri penitentiary we have succeeded in changing it from one of the worst penitentiaries in the country to one of the best, and in so doing I have received valuable aid from the inspections and the suggestions for improvement that have been given me by the members of the State Board of Health.

I understand, Mr. President, that the time of these speeches is limited to five minutes. I have some time yet allotted to me, and there is one other thought I must give expression to before my time is expired, and that is this: You, as a profession, are able to put your own houses in order. You have cleaned up your own Augean stables by driving from your ranks the quacks and abortionists and the charlatans and the impostors. I want to say to you that the State Board of Health in the State of Missouri has been actively on the firing-line, fighting a battle for a clean profession against the elements which foster disgrace and dishonor. In that regard I can say again, to the other profession, the legal profession, if it is to continue in public confidence and approval, it must follow your example, because we have in our ranks quacks and abortionists and charlatans and impostors in our pettifoggers and shysters and ambulance-chasers, and a certain class of lawyers who are all the more disreputable because, with greater capacity for injury in our legislative and judicial lobbyists, in eminent lawyers who, in order to screen rich clients, violate the law and bring the legal profession into disrepute, securing for them immunity.

I trust that in the general beneficial influence that will come from the deliberations of this convention there may percolate down or gravitate up to the legal profession something of that spirit of modern medicine which demands that the learned professions shall also be kept clean.

In conclusion, we welcome you here with interest and enthusiasm. I welcome you not only as the Governor of this State, but also as the Mayor of St. Louis. They go through the ceremony, every four years, of electing a Mayor here [laughter], but I happen to appoint the police power, and therefore I want to say to you, in conclusion, that the immunity that has already been extended to you by Dr. Moore was not a sounding brass or tinkling cymbal. We welcome you with pleasure, not only to our city, but also to our homes and to our hearts.

Address of Mayor Kreisman

HON. H. KREISMAN, Mayor of St. Louis: *Mr. President, Ladies and Gentlemen:* There remains but little for the Mayor of St. Louis to say in extending to you a welcome this bright spring morning. Governor Hadley has truthfully said that he confers by his authority and high office every immunity on you while in St. Louis. We hope that you may have a pleasant stay with us, as our hearts and our homes are open to you, and, my friends, may we have you with us more frequently than during the years that have passed since your last coming. I thank you.

Report of the Local Committee of Arrangements

Dr. W. B. Dorsett, the Chairman, made a brief report of the local committee of arrangements. He announced the places of meeting of the various Sections, the entertainments, the alumni dinners, etc.

The retiring President, Dr. Gorgas, introduced the President-elect, Dr. William H. Welch, who delivered his presidential address, which will appear in THE JOURNAL of June 18.

Society Proceedings

COMING MEETINGS

Maine Medical Association, Bar Harbor, June 29-30.
New Jersey Medical Society, Atlantic City, June 28-30.
North Carolina, Med. Soc. of State of, Wrightsville Beach, June 21.
Wisconsin, State Medical Soc. of, Milwaukee, June 22-24.

ARKANSAS MEDICAL SOCIETY

Thirty-fourth Annual Session, held at Little Rock, May 3-6, 1910

The President, DR. J. H. LENOW, Little Rock, in the Chair

Officers Elected

The following officers were elected for the ensuing year: President, Dr. R. C. Dorr, Batesville; vice-presidents, L. F. Magee, Frostville; J. B. Grammar, Swarcy; and Thad Cothran, Walcott; secretary, Morgan Smith, Little Rock (reelected); treasurer, J. S. Wood, Hot Springs, Pine Bluff (reelected); editor, C. P. Meriwether, Little Rock (reelected); delegates to American Medical Association, J. T. Clegg, Siloam Springs; E. C. Hay, Hot Springs; alternates, B. Hatchett, Fort Smith; L. H. Barry, Hot Springs; councilors, H. R. McCarroll, Walnut Ridge; J. H. Kennerley, Batesville; S. A. Southall, Lonoke; A. D. Knott, Wilmot; H. H. Niehuss, Wesson; L. J. Kosminsky, Texarkana; J. C. Wallis, Arkadelphia; A. H. McKinzie, Dardanelle; C. T. Cannaday, Marshall; and M. S. Dibrell, Van Buren.

The next place of meeting will be Fort Smith, May, 1911.

President's Address: The Progress of Medicine

DR. J. H. LENOW, Little Rock, spoke of the flourishing condition of the society; referred to the early history of the organization, the difficulties met in its early life, and praised the indefatigable, unselfish labors of the pioneers. Their unity of purpose was the highest exemplification of professional ideals; they laid the solid foundation on which present component societies securely rest. He predicted that ere long public health in all the states would be under control and direction of non-political health commissions, selected for skill and executive ability. Closer relations between laity and the profession are foreshadowed by trend of times; together they would make common cause of promotion of measures to combat ravages of disease, and inauguration of a militant plan of leading the public out of sanitary and hygienic ignorance. He predicted a great and glorious future for preventive medicine.

The future honor and dignity of medicine, he said, rested on the thorough training of its votaries, higher standards of medical education and an elastic curriculum. The great need of a thoroughly equipped Board of Health and Bureau of Vital Statistics was referred to with the hope that the near future would bring about its consummation.

The triumphs of medicine are the result of laboratory investigations, and the antivivisectionists are cruelly ignorant of the benefactions conferred on humanity by the discoveries of Pasteur, Lister, Koch, Behring, Flexner, Stiles and Carrel.

It is the duty of the profession to take the public into its confidence and meet the false statements with the unvarnished truths, to open up bureaus of official information available to the public and to educate them in advance of any attempt to limit the freedom of scientific research with legislative restrictions.

Tuberculosis Campaign

A fund of $500 was appropriated as a contribution to the campaign against tuberculosis, to aid in establishing a traveling display and competent instruction from time to time.

Dysentery in Infants

DR. F. T. ISBELL cited as fruitful sources of infection, water, milk, raw fruits and vegetables—malnutrition resulting from improper feeding. Treatment: diet, hygiene, medication, rectal irrigation with bismuth in mucilage of acacia; high and low irrigation with hot normal salt solution.

Infant Mortality

DR. J. T. CLEGG, Siloam Springs: Deaths in infancy up to five years of age exceed the combined mortality from tuberculosis, typhoid and other epidemics; 5,000 infants die to one adult alcoholic mortality. I believe this to be due to heredity, accidents and injuries, improper feeding and lack of hygienic care. The laity should be admonished as to general sanitation and urgent need of wholesome feeding. Nine-tenths of babies are bottle fed. There should be rigid inhibition of fruits, cakes, candies, pastries, and especially strawberries and vegetables grown in contact with soil. Malted milk, infant foods and other so-called substitutes for mother's milk should be condemned. Most satisfactory results are obtained from modified cow's milk.

Acute Otitis Media and Mastoid Abscesses

DR. ROBERT CALDWELL, Little Rock: Predisposing causes are adenoids and hypertrophied tonsils, colds, fevers, diphtheria and other infections. Early paracentesis, irrigation and mastoid operation, if indicated, are the treatment. Extraordinary care is to be exercised in its execution.

Empyema

DR. D. E. BRODERICK, Kansas City: Many children succumb to undiscovered empyemata; more frequently primary than is generally believed. Empyema of newborn is generally due to streptococci; frequently it is a sequel to pneumonia. The onset may be acute or insidious; it is often mistaken for abdominal disease; all hectic temperatures should excite suspicion; sweating and diarrhea may be present. Percussion is a most valuable asset in examination. Forcible percussion is useless; dulness is stationary and not due to position; auscultation is often fallacious. The coin sound is corroborative only; vocal resonance is often ambiguous. Diagnostic difficulties are often very great. Basic diseases are often most puzzling of interpretation by physical methods. Exploratory thoracotomy should be done to clear up the massive signs in chest. Fibrotic lung is often revealed; pneumatic cabinets aid materially. Empyemata of nurslings are often revealed at postmortem. Goodhart's classification is helpful. Prognosis is good in pneumococcal form. Blood picture and *x*-ray and exploratory thoracotomy are paramount in differentiating empyema and pneumonia; strict attention should be given to apical displacements.

Infantile Scorbutus

DR. H. N. STREET, Argenta, condemned canned goods, artificial baby foods and boiled milk. Treatment, he said, consists of administration of orange juice, raw meat juice, unboiled milk, fresh air and sunshine.

Wassermann Reaction

Dr. M. F. Mount, Hot Springs, gave the diagnostic value in 150 cases of suspected syphilis; 40 positive and 110 negative. Technic employed was the same as originally published by Wassermann, with the exception that he used guinea-pig heart antigen instead of syphilitic liver extract. Tests were made in each case with known positive control and known negative control; clinical history of patients unknown. Positive Wassermann reaction means syphilis; active mercurial treatment indicated. Negative means that for the time being treatment is not needed. Patient having had clinical syphilis should have test made frequently over long period of time.

Intramuscular Injections of Mercury

Dr. Eugene C. Hay, Hot Springs: This is a very effective and very popular method. I use grey oil, a modification of Lang's formula (mercury and non-sterilized wool fat), beechwood creosote, camphoric acid and glycerin). Results are most gratifying. The bad results of various clinicians are due to faulty technic. I prefer inunctions as a regular routine and use grey oil only when inunction method fails; in some very stubborn cases I use injections supplemental to inunction with excellent results.

Brain Syphilis

Dr. James H. Chesnutt, Hot Springs: Predisposing causes are trauma, violent strain, mental excitement and alcohol. Symptoms—headache, nausea, vomiting, convulsions, gradual dementia, forgetfulness, complete loss of memory, apathy, delirium, coma and violent insanity; ocular palsy; ptosis; double vision, optic neuritis, blindness. Prognosis is hopeful, and response to treatment may be expected so long as specific changes are present and narrowing of the vessels and atrophy of the brain tissue lacking. However, if one cranial nerve is paralyzed for a year, there is very little hope of recovery from paralysis.

Erythromelalgia

Dr. James H. Chesnutt, Hot Springs, has secured some favorable results from treatment by hydrotherapy, acetosalicylic acid, iron, quinin and strychnin and thyroid extract.

Postanesthetic Acidosis

Dr. J. G. Eberle, Fort Smith: Starving before and underfeeding after anesthesia are exciting causes. I give large amounts of glucose by proctoclysis and hypodermoclysis, and resort to purgation, diaphoresis, enemata of normal salt solution and sodium bicarbonate.

Quinin Anesthesia

Dr. Henry Thibault, Scott: All soluble salts of quinin possess anesthetic properties, but I prefer quinin bisulphate. For inflamed tissues I use quinin and urea bihydrochlorid, as described in The Journal A. M. A., Aug. 8, 1908, April 23, 1910, Oct. 23, 1909.

Preventable Blindness

Dr. John G. Watkins, Little Rock: Out of 193 patients at a state institution, 131 had slight vision, 62 were totally blind, 3 from ophthalmia neonatorum, 36 from trachoma, 23 from various causes. Treatment: Atropin, with insufflations of calomel, nitrate of silver, copper sulphate; hot fomentations for pannus.

Health Conditions in the Delta of the Mississippi Valley

Dr. Vernon MacCammon, Arkansas City: Artesian wells cause great improvement in health conditions. Pure water may be found at a depth of 550 feet. Pernicious malaria is now very rare. Fatal cases are usually due to home treatment with chill tonics. Typhoid fever is rare and generally mild. Drainage and general sanitation and inhibition of use of surface water contribute to general welfare. Pneumonia is rare and hookworm unknown. Soil is black loam, which is unfavorable to the development of uncinariasis.

Severe Prolapse of Uterus, Modern Methods of Treatment

Dr. H. S. Crossen, St. Louis: The old-style hysterectomy should be condemned. The inter-position method is indicated, a modification of the vagino-fixation method of Mackenrodt. For non-operative cases I prefer Gehrung's pessary; second choice is Menge's.

Treatment of Pelvic Cellulitis in the Female

Dr. R. C. Dorr, Batesville: I favor the semilunar incision per vaginam in posterior cul-de-sac under local anesthesia, with insertion of gauze drainage. Palliative treatment comprises administration of salines, hot douches, and either hot or cold applications over abdomen, which ever contributes most to the patient's comfort.

Management of Hookworm

Dr. A. E. Cox, Helena, treated a family of five two years for anemia, using iron, arsenic, nux vomica, etc., without improvement. Condition was relieved by beta-naphthol and castor oil.

Proceedings of House of Delegates

Among the actions taken by the House of Delegates were the following:

Endorsement was given to the Owen bill for a department of health; to the establishment of a Pasteur institute in Arkansas; and to Dr. Wiley's opposition to benzoate of soda as a food preservative.

The delegates to the American Medical Association were instructed to endeavor to secure a new section on the subject of genitourinary diseases and syphilis.

Laws were advocated to require the registration of births and deaths, and better care of insane persons; and to exempt from prosecution a woman testifying against the physician who induced an abortion on her.

The committee on consolidation of medical schools in Little Rock reported favorable progress and stated that the outlook was hopeful for consummation during the present year. The House of Delegates endorsed the proposition of the Medical Department of the University of Arkansas to turn over to the state its grounds, buildings, outfit, money, etc., in order that it might be made a state institution and managed by a non-partisan board.

AMERICAN GYNECOLOGICAL SOCIETY

Thirty-fifth Annual Meeting, held in Washington, D. C., May 3-5, 1910

(Continued from page 1814)

The Use of Vaccines in Septic and Inflammatory Conditions

Dr. E. W. Cushing, Boston: Vaccines, or killed cultures, act by increasing the resistance of the patient. The opsonic index practically is not of much use in acute conditions. Autogenous vaccines are preferable to stock vaccines, except in certain cases of staphylococcus infection. The best results are obtained in the following order: infection from colon bacillus, pneumococcus, staphylococcus. The results are not satisfactory with streptococcus in rapid virulent infections. In chronic infections and in cases of little virulence streptococcus vaccines give satisfactory results, especially in moderate puerperal cases. Vaccines are not successful in acute gonorrheal infections, but are of much service in gonorrheal arthritis. Vaccines are useful in the following conditions: puerperal infections, abortions, infections of bladder and kidneys, appendicitis, abdominal operations, post-operative pneumonia, and abdominal fistula.

Surgical Treatment of Puerperal Septic Infection

Dr. E. E. Montgomery, Philadelphia: The most effective safeguard against the baneful influences of sepsis is the practice of such measures during the parturition and puerperium as will lessen the opportunities for its production. The suspicion of sepsis confirmed, the course of the surgeon must very often still be a tentative one and largely dependent on the period at which the patient comes under observation. Rarely after the diagnosis is definitely determined is it worth while to resort to the use of the curette. The infective germs rapidly pass beyond the superficial structures, so that curetting is ineffective to limit the progress. The removal of the uterus would not always be adequate, so operative procedure should be delayed until it is evident that there exists such a localization as shall make operation effectual in arresting further baneful progress. The results of serotherapy are not always so satisfactory, as not infrequently its employment has been begun too late, or the virulence of the infection is so marked that the best result to be obtained will be a local manifestation of the poison which will still require resort to the knife for the safety of the patient. Extensive peritoneal exudate entirely surrounding the uterus and fixing it and the appendages may be entirely absorbed and the patient restored with functionating organs by rest, regulation of the diet, moderate depletion, and the judicious use of improvised carbonic-acid baths. The constant course of the surgeon should be one of watchfulness, utilizing every force at his command, to conserve the functions of the patient, yet to proceed unhesitatingly to the most radical measures when such seem necessary to the preservation of life.

When Shall We Operate in Puerperal Sepsis?

Dr. John Osborn Polak, Brooklyn, N. Y. read a paper with this title. based on a study of 200 consecutive cases, in which he drew the following conclusions:

1. Each case of post-partum or post-abortal infection must be studied individually, and an accurate diagnosis must be made on the clinical, bacteriologic and blood findings, before any treatment is instituted.

2. Nature is competent in the majority of instances to localize and circumscribe the infection.

3. Curettage, douches and examinations during the acute stage break down barriers and open avenues for the further dissemination of sepsis to the myometrium, parametrium and adjacent tissues, and the danger from curettage increases with each month of pregnancy.

4. Enormous pelvic and abdominal exudates may disappear without operation, and that in time enlarged ovaries, tubes, etc., may assume their proper size and function; and further, that so long as the patient's general condition improves, no surgery is advisable.

5. All operations are attended with less risk after the acute stage of the infection has subsided, and that an exact diagnosis is more easily made at this time.

6. After the uterus is thoroughly emptied, the pelvis should be left absolutely alone, and that we should make every effort to support the patient and increase her natural blood resistance.

7. Extraperitoneal drainage of local foci should be elected when possible, either by incision just above Poupart's ligament, or by posterior vaginal section, and when this is impossible, because of an inability to determine the exact anatomic relations of the local foci, an exploratory laparotomy is justifiable in order to make an exact diagnosis and determine on the safest route for drainage.

8. Operative interference in the acute stage of sepsis is only indicated in general purulent peritonitis, post-abortal pelvic peritonitis, infected tumors in or near the genital tract and uterine rupture, when the rupture has occurred in the course of labor and has been handled outside of a well-managed maternity.

9. Thrombophlebitis is a conservative process on the part of Nature to limit the infection, and any form of pelvic manipulation only tends to break down and separate parts of these thrombi, extending the infection to the more remote parts, thus jeopardizing the patient's life.

Surgical Treatment of Puerperal Septic Infection

Dr. H. N. Vineberg, New York: Surgical intervention, if curettage be not included, comes into consideration in only a small percentage of cases of puerperal sepsis. The selection of these is difficult for want of reliable guides, bacteriologic or clinical, as to the course and prognosis of a given case. Hysterectomy is indicated (a) when the uterus contains putrid placental remains that cannot be removed with the finger or curette; (b) when the uterus contains a sloughing fibroid; (c) when the uterus is studded with abscesses; (d) when the uterus has been subjected to severe traumatism and gives evidence of infection. The status of ligation of the pelvic veins in puerperal septic thrombophlebitis is still *sub judice*. The results thus far warrant a further trial with the procedure. In acute puerperal septic peritonitis good results have been obtained by the Germans with multiple incisions and drainage. Perimetric and parametric abscesses should be approached without entering the general peritoneal cavity. In unilateral pyosalpinx or ovarian abscess, the usual median laparotomy incision should be avoided, and instead of it, one should be made over Poupart's ligament or at the outer edge of the rectus, so as to avoid entering the general peritoneal cavity. Although I am an advocate of major surgical intervention in suitable cases, I have had occasion during the past seven years to extirpate the uterus in only six cases. From this it can be inferred that it is only rarely that major surgical intervention is indicated in acute puerperal septic infection. The vast majority of the patients recover under appropriate general treatment and such minor surgery as the exigencies of the given case may call for.

Is Pubiotomy a Justifiable Operation?

Dr. J. Whitridge Williams, Baltimore, based his paper on a series of twenty-five successful cases and drew the following conclusions:

1. In 25 pubiotomies performed at the Johns Hopkins Hospital there were no maternal and 3 fetal deaths, only one of which is attributable to the operation.

2. All patients were delivered by forceps or version immediately after pubiotomy. There were no injuries to the bladder; there were 6 perineal and 5 deep communicating vaginal tears, notwithstanding the fact that 12 of the patients were primiparæ.

3. The relative infrequency of injury to the soft parts is attributed to restricting the operation to suitable grades of pelvic contraction, and to the employment of Doederlein's technic, but particularly to the extensive manual dilatation of the vagina and perineum prior to operating. The occurrence of such injuries may be still further decreased by making horizontal instead of upward traction when delivering the head through the vulva.

4. The after-treatment is not so onerous as is generally stated, and most of the patients suffer but little. Immobilization of the pelvis is not necessary, a four-inch adhesive strip around the trochanters being sufficient. The patients usually move spontaneously in bed between the second and fourth days, get up between the fifteenth and twentieth, and are discharged on the thirtieth day with satisfactory locomotion. Healing generally occurs by fibrous union, so that there is definite motility between the ends of the bone in at least two-thirds of the cases.

5. The maternal mortality should not exceed 2 per cent., provided the operation is performed by competent operators on uninfected women, who have not been exhausted by previous attempts at delivery.

6. It is indicated in contracted pelves when the conjugata vera exceeds 7 centimeters, and after a test of several hours in the second stage of labor has shown that the disproportion cannot be overcome, as well as in certain funnel-shaped pelves.

7. Prophylactic placing of the saw is indicated prior to breech extractions or versions from transverse persentations when it appears problematical whether the head can pass through the pelvis and the bone sawed through immediately after discovering the disproportion.

8. In multiparæ with a history of repeated difficult labors, or in primiparæ presenting excessive disproportion, pubiotomy is inferior to Cesarean section performed at the end of pregnancy or at the onset of labor; otherwise it does not enter into competition with it, as the former is the operation of choice in border-line pelves after the patient has been subjected to the test of labor, and at that time it is many times less dangerous than the classical Cesarean section.

9. In uninfected women it should replace high forceps, prophylactic version, induction of premature labor and craniotomy on the living child. In how far it may compete with suprasymphyseal Cesarean section must be shown by future observations.

10. It should not be employed in infected patients or after failure to deliver by other means. It should be regarded as a primary operation whose dangers are infection, deep tears and hemorrhage.

11. When the separation between the cut ends of the bone does not exceed 4 or 5 centimeters, the patients recover perfectly and are able to walk and work as well as previously.

12. In view of the fact that the bone section usually heals by fibrous union, a certain degree of permanent enlargement of the pelvis may follow, particularly in the transverse diameter of the outlet, and less so in the conjugata vera. Under the influence of the hyperemia incident to a subsequent pregnancy, this may occasionally become markedly exaggerated and be sufficient to permit spontaneous labor. Should this not occur, a second pubiotomy may be performed; while Cesarean section should be limited to those cases in which the pelvic contraction is marked and the child large.

Fibromyomata of the Uterus

Dr. I. S. Stone, Washington, D. C., gave his views on the various practical points in connection with the general subject, such as the age of patients, the complications frequently encountered in performing hysterectomy, and the pathologic changes found in the tumors themselves. He reported 160 abdominal hysterectomies; 30 were complete hysterectomies, but the ovaries were not always removed. He thinks the operation at present is nearly as safe as ovariotomy, so far as life-saving goes, but the morbidity is not so low as in the latter operation. The complications resulting from the degenerative changes in the tumor, the danger of sepsis from the proximity to the vagina, and the greater exposure of pelvic connective tissue in hysterectomy will always be considered more productive of mischief than the conditions which follow in the wake of ovariotomy. He gave the question of mortality much attention and quoted from the reports of operations in various hospitals to show marked improvement in results during the last decade. The average mortality, he said, is now about 4 per cent., but many operators have obtained a much lower rate.

Total Absence of the Vagina and Uterus; Right Pelvic Kidney; Absence of Left Kidney; Tubes and Ovaries on Both Sides in the Inguinal Canal

Dr. Thomas S. Cullen, Baltimore: The patient, aged 17, white, came complaining that she had never had menstrual periods. On examination I found total absence of the vagina, but by rectal examination was able to detect a mass filling the right half of the pelvis, which I thought might be the uterus which retained menstrual flow. An incision was made between the bladder and rectum until the mass was reached. It was, however, found to be hard. The abdomen was at once opened and a somewhat irregular mass was found filling the right half of the pelvis. This on its inner aspect had a definite cleft which suggested the pelvis of a kidney. A hand was carried up into the right renal pocket, but no kidney was present at that point. Examination of the left side failed to reveal any left kidney. The mass was evidently a right pelvic kidney. There was no uterus. Half of the right tube emerged from the inguinal canal. The remaining portion of the tube and the corresponding ovary lay in the inguinal canal. A small loop of round ligament was seen emerging from the inguinal canal. On the left side the tube and ovary could not be seen, but could be felt in the inguinal ring. A small portion of the round ligament was discernible.

Dr. Cullen demonstrated a specimen of adenocarcinoma of the Fallopian tube coming from a patient, forty-six years of age. The chief interest in this tube lay in its immense size. It formed a tumor 14x12x10 cm. Near the uterus the tube was normal in size. After it had passed out 5 centimeters, it was 5 centimeters in diameter, and its outer and occluded end was 10 centimeters in diameter. The great distention of the outer end of the tube was in part due to an accompanying hydrosalpinx. The growth was limited almost entirely to the inner surface of the tube. It was of a distinct papillary variety. The left tube was also involved in the carcinomatous process. This was one of the largest carcinomas of the tube on record.

Repair of Inaccessible Vesicovaginal Fistulas Following Hysterectomy

Dr. George Gray Ward, Jr., New York: The important steps which lead to a successful result in the method employed are: (1) The differentiation from a urethral fistula by distention of the bladder with an anilin solution; (2) the employment of deep paravaginal incisions as described by Schuchardt; (3) a longitudinal incision on the anterior vaginal wall from the urethra to the vaginal vault through the fistula and extending into the posterior vaginal wall, and a lateral incision extending the full width of the vaginal vault; (4) the thorough separation of the base of the bladder from the entire anterior vagina and vaginal vault, being careful to commence the dissection in the lower vagina where there is an absence of scar tissue to establish the line of cleavage; (5) evisceration of the bladder into the vagina by means of a sound or similar instrument passed through the urethra; (6) the closure of the opening in the bladder separately from the vaginal incision.

Influence of the Trendelenburg Position on the Quantity of Urine Excreted During Anesthesia

Dr. J. Wesley Bovée, Washington, D. C.: Having recently studied 8 cases of ether anesthesia and 8 of chloroform, I believe that the results demonstrate that almost no urine is received in the bladder while the Trendelenburg position is being employed. If it can be concluded that the renal function is greatly lessened while the patient is in the Trendelenburg position, then the dangers of that position are at once appreciated. In renal inefficiency, and in cardiac and arterial lesions, it would seem the use of the Trendelenburg position would introduce a special element of danger and this would be more marked when ether was used than when chloroform was employed as an anesthetic.

Postoperative Treatment of Abdominal Section for Pelvic Disease

Dr. Brooks H. Wells, New York: Getting the patient out of bed early after operation encourages her, lessens nausea, promotes an earlier return of appetite, increases peristalsis, makes the use of the catheter seldom necessary, makes the bowel movements easier so that there is less necessity for purgatives, improves the respiration, lessens the tendency to pulmonary complications, prevents loss of muscle tone, and greatly facilitates a rapid convalescence. The contraindications are: 1. Shock or general weakness, as expressed in a rapid and weak heart, so that we might fear cardiac failure from the upright position. 2. Cases in which, with a long median incision there has been much tension required in bringing together the fascial edges. 3. In patients who develop septic temperatures or deep wound infections. Of the patients whose cases form the basis of the paper, over 100 have been operated on through a transverse incision, and of these none has developed hernia. Two patients in whom median incisions were used are known to have developed hernia, but neither was allowed out of bed early.

Report of the Committee of the American Gynecological Society on the Present Status of Obstetrical Education in Europe and America

This committee, consisting of Drs. E. B. Cragin, J. C. Edgar, C. M. Green, E. P. Davis, J. W. Williams, J. C. Webster and B. C. Hirst, chairman, recommends that the teaching of obstetrics should occupy at least two years of the medical course, and that those expecting to practice obstetrics should be urged to avail themselves of elective opportunities, and that the number of labor cases personally attended by each undergraduate student should be at least six, under supervision and instruction.

The committee recommends all the known methods of teaching this branch of instruction, namely, didactic lectures, clinical lectures, clinical conferences, ward classes and touch courses, hospital and out-patient instruction, manikin practice in operative obstetrics, and recitations. Of the first three methods the committee recommends specially clinical lectures and conferences. It recommends that ample facilities should be afforded students to make antepartum examinations including inspection, abdominal palpation, pelvimetry, fetometry, vaginal examinations, etc. The committee recommends that a two weeks' hospital residence should be required before the out-patient practice. It is recommended that as obstetrics at present includes pregnancy and parturition, their complications and consequences and the complete recovery of the woman after labor, that obstetric instruction should include the medical and surgical treatment of these conditions. The tendency of obstetrics to become more surgical in practice and to require a surgical training, is evidenced by the fact that in the medical schools of Europe, and in more than one-third of the first fourteen medical colleges of this country, the chairs of obstetrics and gynecology are combined under one head.

On motion, the report of the committee, with its recommendations was adopted.

Cesarean Section for Impassable Contraction Ring

Dr. Robert L. Dickinson, Brooklyn, N. Y. . Apart from a consideration of contracted pelvis, or relative disproportion between the passage and passenger, or blockade by scars or tumors, section for impassable con traction ring is warranted when the following conditions ar present: (1) Child living and not definitely enfeebled or endangered by the length of labor or by unskilled attemp s at extraction; (2) the ring refusing the relax under morph in or complete anesthesia, and to yield to patient manual dilatation by a skilled obstetrician; (3) mother in fair condition for a laparotomy and not infected; (4) request by patient and husband that a somewhat increased risk to the mother be assumed for the sake of obtaining a living child in lieu of embryotomy. These indications are perfected if at a previous labor in expert hands, this same condition of the contraction ring has caused the loss of a child not unduly large. This holds good whether the ring is in advance of the head or about the neck. The association of a rigid ring with other reasons for section is frequently present.

AMERICAN ORTHOPEDIC ASSOCIATION

Annual Meeting held in Washington, D. C., May 3-5, 1910

The President, Dr. Augustus Thorndike, Boston, in the Chair

President's Address: Our Relations with the Community, Especially with Medical Men

Dr. Augustus Thorndike, Boston, urged orthopedic surgeons to take greater interest in the work of other members of the medical profession, and to try by every means in their power to interest other physicians in the work of the orthopedic surgeon.

SYMPOSIUM ON POTT'S DISEASE

Pott's Disease: Causes of Paraplegia and Their Bearing on Treatment

Drs. Charles F. Painter and George C. Moore, Boston, discussed the various causes for the paralysis occurring in the course of Pott's disease, both in theory and as the result of actual observation; the clinical phenomena and the behavior of the cases with and without treatment, including the rationale of treatment. The following conclusions were reached:

Scoliosis occurring in Pott's disease should be regarded, not as a regrettable incident in the course of the disease, but as an evidence of the activity of a tuberculous process. This fact should cause redoubled efforts on the part of the physician to control the underlying disease. So long as this exists, one should be cautious in giving a prognosis as to the cure of the condition. In seeking to relieve this condition, one should be guided by the character of the symptoms and be loath to permit operative interference until further and more convincing evidence has been obtained that surgery can play any part in the cure of these conditions.

Advantages of Braces over Plaster Jackets in Pott's Disease

Dr. Henry O. Feiss, Cleveland: A brace will do all that a jacket can do. Braces can be readjusted to suit changes in size; and they are lighter than the plaster jackets. The parts are accessible, when braces are worn, so that the patient may be bathed. The jacket can be removed by the mother almost as easily as a brace, and the temptation to remove it is greater. The mother should be thoroughly instructed how to adjust the brace, which meets all the mechanical requirements, and is lighter, cleaner, cooler and more scientific than the plaster jacket.

Support for the Spondylitic Spine Obtained by Healing in Steel Bars Attached to the Vertebræ

Prof. Fritz Lange, Munich: The kind of metal used is of much importance. In this minor operation, designed to immobilize four or more of the vertebræ, I use steel wires, 5 mm. thick and 10 mm. long, which have been carefully plated with tin. The operation is applicable only in the early stages of the disease, before the appearance of deformity or when the deformity is slight. The wires employed have tin knobs at their upper and lower ends; and a thread is tied under the knobs, to prevent sinking. Provision is also made to fasten the apparatus to the spine. This new operation, I believe, gives the best chance for spondylitis to heal quickly and without great pain.

Discussion on Pott's Disease

Dr. Newton M. Shaffer, New York: In Pott's disease in the dorsal area, if we can eliminate the trauma of respiration, we are taking a long step in the right direction. Pott's disease below the respiratory region requires very simple support. The movement of the respiratory area is controlled by Nature and by the patient himself, who makes an effort to limit respiration in the affected area.

Dr. S. J. Hunkin, San Francisco: In a majority of cases, the steel braces can be applied with more efficiency than can the plaster jackets; but a plaster-of-Paris jacket is not heavier than a steel brace, if properly made.

Dr. Charlton Wallace, New York: In selecting the treatment for Pott's disease, we must divide the cases according to the stage of the disease. The gist of the whole position is that all orthopedic surgeons are aiming to give the patient the benefit of the best treatment, the main object of which is relief from the superincumbent weight. The non-ambulatory treatment seems to me ideal; but we hate to see children put to bed for several years, so the surgeon tries to get something that will yield proper ambulatory treatment. It is foolish to say that we can absolutely immobilize the spine; therefore, our aim is to get as near to absolute fixation as possible. In the early stages of the disease, when the patients have been taken from bed, nothing can be more advantageous than the plaster jacket, which can be made to weigh no more than a pound or a pound and three-quarters. In patients who are moving around, I do not believe that we can beat plaster-of-Paris. For the convalescent cases, most of us use a brace. Dr. Lange has brought before us a method of treatment which is hazardous, but admirable in the hands of an expert. I should, however, be afraid to try it.

Dr. David Silver, Pittsburg, Pa.: Regarding plaster jackets as opposed to braces, it is merely a question of which we can handle best. The deformity should be corrected during recumbency, and not with the jacket or brace. At the Children's Hospital in Pittsburg, we change the braces ourselves, and do not allow the parents to touch them.

Dr. Ansel G. Cook, Hartford, Conn.: The orthopedist has in these cases a disease to treat and a human being to manage. Sometimes the patient needs the bed; sometimes, fresh air. There are times when the jacket is better, and there are other times when the brace is very much better. The question is, what advantage has either method over other methods.

Dr. H. Augustus Wilson, Philadelphia: No case of Pott's disease has ever been cured by braces or by plaster jackets. Relief from the superincumbent weight is simply one of many means to the end. If recumbency in bed does not interfere too greatly with circulatory activity, then it is essential for a period of time. In many cases, I have seen cure without resort to apparatus. The form of apparatus is of minor importance, but constitutional treatment is of great importance. Whether Dr. Lange's method of getting support of the spinal column without restraint of the respiratory organs or of the body is to be of much use to the ordinary orthopedic surgeon, is questionable.

Dr. Robert S. Lovett, Boston: Neither a brace nor a jacket is thoroughly efficient mechanically, although it takes off some of the superincumbent weight. Great as are the objections to the treatment of Pott's disease by recumbency, it is the only efficient surgical treatment for tuberculosis of the spine. In comparing braces and plaster jackets, we are comparing two relatively inefficient methods of treatment.

Dr. Reginald H. Sayre, New York: I believe that, rather more frequently than Dr. Painter seems to think, the superincumbent weight and bending forward of the spine are factors in the production of these hemiplegias. I do not think that treatment with recumbency, unless supplemented by longitudinal traction or hyperextension, gives adequate support. A jacket without a jury-mast is often a very inefficient means of support. The mast must have a chin support and exert pressure against the anterior part of the neck, to keep the upper part of the body well bent backward. The difficulties in keeping the bones at rest are insuperable. Dr. Lange's method should not be used by anyone who has not very skilful technic. In suitable cases I believe it would be useful; but in the badly kyphosed cases, I do not know that we should get the support needed.

Dr. B. K. McKenzie: I think that all these patients, so far as possible, should be treated by recumbency during the active stage of the disease; but if the recumbency has to be in a house, I am not sure that I should choose it in preference to efficient mechanical support with a brace or a jacket. The patient should live out of doors, day and night; and when the sun shines, he should be directly exposed to the sun's rays.

Dr. G. G. Davis, Buffalo: I have felt for a number of years that our aim should be to progress in the way of shortening the treatment. The main drawback of orthopedic surgery is that the patients are too long under treatment. Dr. Lange has submitted his method as one of the means by which the period of treatment can probably be shortened, and it behooves us to give it a fair trial.

Dr. James K. Young, Philadelphia: I think that there is a field for laminectomy in these cases, when the paralysis has existed a year or eighteen months. After that period, if there is no improvement in the symptoms, or if symptoms of abscess can be verified by the *x*-ray, operation should be performed.

Dr. Albert H. Freiberg, Cincinnati: Treatment by recumbency is one of the oldest methods in Pott's disease. For some reason, we went away from it; and for some other reason, we seem to be coming back to it. It was observed that, as the first result of putting the patients to bed, they made great improvement. Then, after recumbency had been continued beyond three months, the patients retrograded. We have now learned that something more must be done for the general condition; and we have added to the recumbent treatment, the open-air treatment and the care of the patients' regenerative processes. It is only by a combination of these that such remarkable results have been accomplished. I think that Dr. Lange's method offers great promise for a certain class of patients—those who have Pott's disease in its incipiency. If we delay the application of the splints until the later stages, we shall be applying them when the spine is no longer able to respond by the production of the new bone-tissue in the place of that destroyed by the disease, and shall be depending entirely on the mere splinting for the ultimate result.

Dr. Emil S. Geist, Minneapolis: What does Dr. Lange do regarding the future growth of the patient? It has struck me that in these incipient cases, which are usually in children, we ought to consider this point, if the steel is to remain attached to the vertebræ.

Dr. Charles F. Painter: Sclerosis is the keynote of the treatment of Pott's disease by laminectomy. It depends on proliferation of connective tissue; if this is inside the pia, it cannot be touched by laminectomy. In cases in which the granulation process has produced the changes outside the dura only, laminectomy will relieve the paralysis. It must not, however, be performed until the process of shrinking of the scar tissue has sufficiently progressed. The paraplegic condition that we cannot touch for two years are not the class of cases that can be relieved at the termination of the two years. The cases that get well do so because the process is outside the dura.

Dr. H. O. Feiss: I agree thoroughly with Dr. Lovett that recumbency is the ideal treatment, when it can be carried out. I did not say that the principles of the plaster jackets were wrong, but that they could be carried out more accurately and scientifically by means of braces.

Dr. Fritz Lange: The operation which I recommend should be carried out as early as possible, since the object is to secure the healing of the process before much destruction of tissue has occurred. I should not, however, hesitate to employ this method in cases in which the disease has progressed farther. In the case in which the longest time, two years, has elapsed since I performed the operation, I have not been able to observe, by means of the *x*-ray that the vertebræ in the part of the spine spanned by the wires are smaller than those immediately above and below the point operated on. Should I observe any interference with the growth of the spine, I should not hesitate to remove the steel wires after the disease has healed.

AMERICAN PEDIATRIC SOCIETY

Annual Meeting, held in Washington, D. C., May 3-5, 1910

(Concluded from page 1890)

The Use of Bacterial Vaccines in Children's Diseases

Dr. John M. Howland, New York, and Dr. B. R. Hoobler, New York: This paper is based on cases occurring in the Bellevue Hospital during the last ten months. The infections were the usual ones found in children's hospitals. Unless marked specific results are obtained, conclusions are difficult to draw. There were 31 cases of localized infection with the *Staphylococcus aureus*. They yielded to four or five inoculations of the autogenous vaccine. Of general systemic infections with the staphylococcus there were 3 cases, all of which recovered. The experience with localized infections treated with autogenous vaccines has been very satisfactory. Of streptococcus infection, localized, there were 13 cases, which yielded much less to vaccine treatment than those due to staphylococcus. Of general streptococcus infection, 5 were cases treated. In fifty pneumococcus infections treated with stock pneumococcic vaccine used, we are not able to report any beneficial results nor any unfavorable ones. We are not impressed with the effects of the treatment in vulvovaginitis.

DISCUSSION

Dr. F. S. Churchill, Chicago, reported a case of meningitis due to staphylococcus infections, in which an autogenous vaccine was used, followed by speedy recovery.

Dr. Henry Koplik, New York, said that in the staphylococcus infection his results agreed with those of Dr. Howland; with the streptococcus infections results had been discouraging.

A Case of Thymic Asthma

Dr. A. D. Blackader, Montreal: I wish to report a case occurring in a child ten months old, suffering from severe dyspnea. The child was nursed for six and one-half months, then weaned because of the mother having German measles. It had a severe attack of bronchitis, but with no cyanosis; respirations at that time were of a croupy character; no dulness then over area of thymus. Some symptoms of rachitis developed. Then the child apparently caught a fresh cold; breathing was rapid and difficult, but without cyanosis. This condition increased and there was a distinct area of dulness. Operation was proposed to raise the thymus, but the surgeon declined. The child died the following morning. I have been unable to find the report of a similar case. There was a large cystic mass between the trachea and the esophagus. It is believed that it developed from a bronchial cyst.

The First Sound of the Heart in Children

Dr. F. Forchheimer, Cincinnati: If one were inclined to believe after so long a time in which the normal heart sounds have been studied there is a concensus of opinion among authors in regard to their production, a review of the literature would be disappointing. The statements of different authors are so much at variance as to seem almost incredible. In connection with the normal first sound of the heart there still exists much difference of opinion, but certain modes of its production are accepted by the majority, many of whom differ as to details. In children the pitch is high, depending on the age and size of the child, from *g* or *a*, soprano, below the staff, gradually becoming lower until it reaches double *b*, soprano, below the staff. The dominant factor in the production of the first sound is the systolic contraction of the myocardium; next to this in importance is the tense auriculoventricular valves; then those vibrations occurring in the large vessels; and lastly, the vibration of the semilunar valves. Instead of only two factors for each side of the heart,
four in all, we are forced to accept four fo
is, eight as the number of component par
sound. In the child heart the conditi
plicated; as the organ is slowly dev

are still more com-
ing from the conditio
of adult life, there must b
on the periods of development
as expressed by the ratio of th
the weight of the body is the mos

important factor; elasticity of the myocardium must also be considered. Whoever undertakes to make a diagnosis of a heart lesion in a child in an offhand manner immediately stamps himself as a dilettante in heart diseases. The manner of differentiating organic from other valvular bruits in children under three as given by Hochsinger, that under 3 years all bruits in the heart are organic is to be deprecated, although this statement has been widely accepted. In children under 3, functional and accidental bruits are found very commonly. They depend on myocardial conditions. Systolic bruits are found in forms of acute myocarditis due to diphtheria, typhoid, rheumatic fever, variola, gonorrhea and septic pyemia. In chorea the bruit is produced by acute endocarditis. The development of the elastic tissue must be taken into consideration in explaining this bruit; if there is a disparity between the strength of the myocardium and the resistance of the elastic fibers there will result more or less of an inequality in the conus arteriosus, which acts as an obstacle; when the blood passes over this a bruit is produced. That the anemic bruit is produced directly by anemia is a matter of some doubt. In many cases of anemia there is no bruit, and many bruits are attributed to anemia which are due to other causes. It is impossible to diagnosticate anemia by listening to the heart.

DISCUSSION

Dr. W. P. Northrup, New York: I wish to emphasize the fact that many murmurs from unexplained causes in children under three do disappear.

Dr. S. McC. Hamill, Philadelphia: I think the explanation offered by Dr. Forchheimer is a valuable one. I have been convinced that there must be more than one etiologic factor for these murmurs, and I am glad to hear Dr. Forchheimer express the view that Hochsinger's statement is incorrect.

Dr. F. S. Churchill, Chicago: I once had a case of a child with nephritis who developed an acute arthritis of the knee joint, when a systolic murmur was heard, which gradually disappeared. Blood cultures in this case were negative.

The Value and Limitations of Cold Air in Acute Respiratory Conditions

Dr. J. P. Crozer Griffith, Philadelphia: There should be a clear idea of what really constitutes cold-air treatment. It might be used in three ways: first, exposure of the body to cold air; that is not what any of us are doing, because the children are thoroughly wrapped up and the body kept warm; second, breathing of cold air; but the cold air does not enter the lungs as cold air; third, the action of cold air on the face. There is question about the benefit of fresh air, but we must not forget that it is not a new thing by any means. Whooping-cough had been treated that way for many years and also phthisis in adults. The employment of cold air in the treatment of acute respiratory conditions had its limitations, and not every case of such disease is to be exposed to cold air.

DISCUSSION

Dr. L. E. LaFetra, New York: At the Baby's Hospital, in which they have instituted a "cold ward," in which the temperature is kept at about 50 F. from November to April; next to this is a regular ward where the temperature is 70 F.; and in connection with this a steam room for administering vapor inhalations. From the cases that have been treated in the cold ward and in the adjacent warm ward, the following conclusions may be drawn: 1. In the acute congestive stages of inflammations of the upper respiratory tract (rhinitis, laryngitis, bronchitis, especially of the small tubes, with or without bronchial pneumonia) warm, moist air is of greater help than cold dry air. 2. In lobar pneumonia, with high temperature and little or no bronchitis, cold dry air is of great advantage. The same is true of pulmonary tuberculosis and of empyema. 3. After the acute stage has passed, and when there is no inflammatory spasm of the larynx or bronchi, the cold-air treatment is of advantage in cases of rhinitis, laryngitis, bronchitis and bronchial pneumonia.

Dr. W. P. Northrup, New York: The essential of the fresh cold-air treatment is partly that it should be circulating, moving air.

Dr. E. E. Graham, Philadelphia: From the standpoint of private practice one is soon convinced that unless you get cold air in the sick room you do not get fresh air; the room that is not cold is apt to contain vitiated air.

Dr. John Howland, New York: It is almost the invariable experience that children with acute infections do better in cold air than in warm air, and with pneumonia they do better out of doors in winter than in summer. The rise in blood pressure accomplished by putting the patient out doors can only result in benefit in these cases in which fall of blood pressure is a prominent symptom.

Dr. A. D. Blackader, Montreal: I agree as to the value of increasing blood pressure in the latter stages, but think that in the earlier stages lowering of blood pressure is indicated. I advocate fresh cold air because I feel that the child is getting more oxygen and a certain amount of stimulation to the respiratory center, rather than because of increased blood pressure.

Dr. T. S. Southworth, New York: I wish to emphasize particularly the advantage of cold fresh air in the prevention of acute respiratory diseases. In our wards the temperature is now kept so low that the faces and hands of the children often looked rather blue and chapped, but acute respiratory infections among them are now very rare.

Retained Intubation Tube; Abductor Paralysis (Diphtheria); Recovery

Dr. W. P. Northrup, New York: I wish to present the following unique case: A fifteen months' old boy had been suffering with diphtheritic laryngeal stenosis and wearing intubation tube two weeks; had had whooping-cough 4 months before contracting diphtheria. He came to the hospital with urgent dyspnea and immediate intubation was attempted by the ambulance surgeon. Intubation was unsuccessful, but efforts resulted in relief. When I tried intubation the tube met with obstinate resistance. The smallest tube was gently forced past the obstruction and relief followed. Artificial respiration was immediately necessary. The first diagnosis was catarrhal laryngitis in a larynx recently injured by diphtheria and intubation, a marked nervous element being added from the recent whooping-cough. There was pseudomembrane visible, tonsils very large, coarse râles everywhere over both lungs. Two days after admission respiration was free, but signs of consolidation appeared at one apex. After three days tube was taken out; after brief sleep child choked up and ceased to breathe; with great difficulty tube was reinserted and artificial respiration again used. Quick emergency relief was required a half dozen times in the first few days. He coughed out all the tubes put in; and required intubation 40 times during stay in hospital; increased sizes used. Patient was discharged, but again returned with dyspneic symptoms and is still in the hospital. The secondary dyspnea would seem to have been due to diphtheritic laryngeal paralysis, plus subglottic swelling, complicated with marked nervous spasm.

Bacteriology of the Blood in Early Life

Dr. F. S. Churchill, Chicago: Medical literature is replete with reports of the study of the bacteriology of the blood in adults, but few reports have been made of such study in infants and children. In scarlet fever alone has such work been done. Together with Dr. Clarke, I have studied the series of cases reported. The study consisted of 50 examinations on 44 infants and children and the study of 16 cases post-mortem. As blood cultures in adults have yielded information of such scientific interest and value, that there is need of more of this kind of work in the study of diseases of infants and children, as it is reasonable to suppose that blood cultures in early life may be of even more value than in later life.

DISCUSSION

Dr. L. Emmett Holt, New York: The taking of cultures in the infections of infants has not appealed to me much as a practical procedure, because the difficulties are great and the results not commensurate with the risks.

Dr. Henry Koplik, New York: With very young infants I have had the same difficulty as Dr. Holt; it is difficult to get enough blood to make a satisfactory culture, and in these cases the results have not been as satisfactory as with older children. However, there are some cases in which the results are excellent.

Dr. Isaac A. Abt, Chicago: In the hospitals cultures should be made. I found that they throw a very important light on many conditions. The efficacy of the work depends much on the expertness of the man making the blood culture.

Dr. David Bovaird, New York: I wish to advocate the taking of blood cultures in children, and as the technic is perfected the same sort of accuracy as now obtained in adults will be gotten in the study of the diseases of children.

Dr. David L. Edsall, Philadelphia: I have come to rely on blood cultures as the most valuable means of diagnosis in obscure conditions of older children. I think it a method of great value.

Dr. F. S. Churchill, Chicago: While we do not know a great deal about the subject of the bacteriology of the blood in infants at present, and cannot draw any very definite conclusions, it is important to go ahead with this study and any accurate method that may add to the knowledge of these conditions should be given a thorough trial.

Acute Pericarditis in Children

Dr. David Bovaird, Jr., New York: [*This paper consisted largely of charts showing in detail the studies carried out on a series of cases, the first one comprising a series of 14 cases of acute pericarditis in children under the age of 5, at the New York Foundling Hospital, during 8 years.*] Acute pericarditis occurs at practically all ages. There is an astonishing prevalence of boys in the list. It is in most cases a secondary affection; secondary particularly to affections of the lung, pleurisy or pneumonia. It complicates bronchopneumonia or lumbar pneumonia without distinction. Of the 14 cases, 11 were purulent. The second chart comprises a series of 17 cases of pericarditis, acute. Twelve out of the 17 were cases of rheumatic fever, and in almost all the type of inflammation was fibrinous or serofibrinous. It is important to recognize pericardial dulness in the fifth right interspace, and especially the progressive increase of this dulness; if the right and left limits of cardiac dulness are outlined, within 12 to 24 hours it is possible to demonstrate any increase of this dulness. Its differentiation from acute dilatation of the heart is of importance. The *x*-ray as now employed is of great value in the diagnosis of these conditions, and it is now possible to make out pericardial effusions with great accuracy by this means, so that the aspirating needle can be used with greater safety. Aspiration at the fifth interspace should be done.

DISCUSSION

Dr. Henry Koplik, New York: There is great difficulty making a diagnosis of pericarditis in young infants because of the fact that the heart lies in such a way that the effusion first begins in the posterior superior angle, and unless the fluid approaches 200 c.c. a diagnosis cannot be made. There is danger in aspiration, as the exudate is apt to become encapsulated and partitioned off and one may get into the main sac and pierce the ventricle.

Dr. Isaac A. Abt, Chicago: The great danger of puncture in all these cases is that it is very difficult to differentiate between a serous and a purulent effusion and the so-called acute adhesive pericarditis.

Chylous Ascites in Infants

Dr. D. M. Cowie, Ann Arbor: A case was seen a little over a year ago with the following history: Delayed birth; difficulty in labor due to the large abdomen; the abdomen greatly increased in size after birth. *X*-ray showed no tumor; scrotal sac was tense, but gentle taxis could push fluid up into abdominal cavity. Child recovered, though it still has attacks of occasional blueness. It was at first thought that there was a heart lesion of some kind. Orthodiagraph showed the right part of the heart further to the right than normal in a child of that age and size. The right heart was very much enlarged. The case was probably due to some form of congenital heart disease. Analyses of the fluid showed that all the elements of chyle were contained in the fluid.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

Organization in Texas

The following address by Dr. W. B. Russ of San Antonio, Texas, President of the State Medical Association of Texas, was delivered at the forty-second annual session held at Dallas on May 10, 1910. Dr. Russ' address is particularly notable and commendable as a review of conditions previous to reorganization and the changes wrought in the last ten years. With the exception of a few paragraphs regarding purely local conditions, the address is published entire.

Ten years ago the state medical association had enrolled 296 members. Many parts of the state were not represented at all. The association business was transacted by the mass-meeting plan, which meant that many parts of the state had no representation, and that the city in which a meeting happened to be held always had control of affairs. The organization had, after thirty years of existence, failed to secure the enactment of any public health legislation except a practice act, which in some respects was worse than no law at all. The press was antagonistic and the public out of sympathy with the profession. The endorsement of any measure before the legislature by the physicians of the state was a solar-plexus blow to that measure. All public health laws proposed by the association were treated with derision and contempt.

Texas was a land of promise and of profit to magnetic healers, hoodoo doctors, itinerant fakers, universal specialists and fraud doctors of every persuasion. No medical cult was so absurd in its claims, no fraternity of grafters were so brazen in their methods but that their unworthy sons could find a haven of rest in Texas. Many of these, fortified with the legal standing gained in those golden days for quackery and ignorance, remain with us still as unpleasant reminders of the time when the medical ignoramus and the fraud doctor enjoyed a better standing with the press and the public, the politicians and the courts, than did the reputable members of the medical profession.

The enterprising nostrum manufacturer was unhampered by any check. The doctor was the middle-man through whom the manufacturer reached the public with his products, and yet the doctor himself did not and could not, have any information concerning the true nature of the medicines he was assisting in placing before the public, except such information as the proprietor and his agent with the sample-case saw fit to impart. Subsequent developments have shown that in those days many of our most respected manufacturing chemists, in addition to the reputable products offered through the doctor to his patients, also supplied the public, either directly through dummy concerns or indirectly, with the nostrums flagrantly advertised in the lay press, on bill-boards and through the medium of the street faker. The great mass of the medical profession knew nothing about organized medicine and its possibilities, and in many parts of the state were engaged in bitter and senseless feuds, which were a disgrace to the profession and ruinous to the men so engaged.

To-day what a contrast! Our 155 county societies, with a combined enrollment of about 3,100 members, as if by magic, have accomplished wonders. The old mass-meeting has given place to a truly representative plan of government by which every county society has a voice in managing the affairs of the association through a trained delegate of its own selection. The senseless and disastrous bickerings and quarreling of the old days have given place to an era of better understanding between the members of the profession. The great campaign of education carried on by the county and district societies and by our state journal has enabled us to win the confidence and friendship of the press and of the public. The law-makers now are beginning to understand that the State Medical Association of Texas does not ask for class legislation, that it seeks to secure the enactment of only such laws as are clearly in the interest of the public health. The records of the last two legislatures clearly demonstrate this, as the enactment of the following legislation will show:

The medical practice act.
The anatomical act.
The board of health act.
The tuberculosis sanatorium act.
The leprosarium act.
The pure food and drug act.

Not a single one of these laws could be made to serve a narrow or selfish person. They are clearly worthy of our great profession and are in the interest of the people of Texas. Our present practice act forces medical schools to adopt high standards; broadly defines the practice of medicine so as to include every one who treats, or offers to treat, the sick; provides for proper registration; fixes heavy penalties for grossly unprofessional conduct of a character likely to deceive or defraud the public, and has already been hailed as a model law by not less than a dozen other states. Contrast this with the practice act under the old régime, which discriminated in favor of all practitioners, except the members of the regular profession, which placed no restriction on the doctors and healers who did not prescribe drugs and allowed those who happened to hold peculiar views about the administration of drugs to set up their own standards. Yet this law was the only law passed in the old days, and even it was not passed until it had been given the reverse English. Not a single law asked for since our reorganization has failed to pass. . . .

The many activities in which the association is engaged in the great work of carrying out the purposes for which it was organized and for which it exists are well known to you. That its progress and growth are due largely to the influence of our state journal, I am sure you will agree. Under the able and efficient management of our secretary-editor, the *Journal* has, since its organization in 1905, made a determined and successful fight for the elevation of medical school standards for perfection and final passage of all the medical laws we now have on our statute books. It has unified the profession as no other agency could, and without its influence it is doubtful if any of the many reforms for which we take credit could have been accomplished. Our editor is regarded everywhere, in Texas and outside of Texas, as the ablest state journal editor in the country, and the *Journal* is without doubt the best publication of its kind. During the first years of its existence, Dr. Chase donated the use of his private office to the association to be used as journal headquarters, and he has for several years, in quarters entirely inadequate to the needs of his office and at great personal sacrifice, labored day in and day out for the upbuilding of the association. He has steadfastly refused to use the *Journal's* pages to defend himself against villainous attacks of his detractors and has with as much patience as I have ever known a man to display, allowed himself to be misrepresented and hounded by the influences opposed to the policies of the association and to the very existence of its journal. What this work has cost him in dollars and cents alone few men in the profession would have been willing to sacrifice. His path has been a thorny one, but, under every circumstance, he has shown himself to be a man worthy of the love and respect of the profession and deserving well at the hands of the public. Had it not been for the willingness of the secretary, of the trustees, of some of the councilors and others in the profession, to sacrifice both time and money in the service of the association, our finances would have been wrecked long before this and the reforms which we have accomplished would not have been accomplished. This fact is understood and appreciated by most of you. The small pittance that is collected in dues would never have been sufficient to meet the extraordinary expenses incurred in making all the fights we have had to make. No ordinary man would have been willing to make the sacrifices that the trustees and the editor have made. These considerations have no doubt influenced many of the friends of the association to refrain from making complaints, when in their judgment mistakes have been made, and from offering suggestions for possible changes in the methods employed by the men on whom has been placed the responsibility of managing the association's affairs. That criticisms and suggestion, having for their object the upbuilding and improvement of the association, have been needed, and will be needed in the future, every one will admit.

THE OPPOSITION

This, then, brings us to the consideration of a matter to which I desire particularly to direct your attention—a matter which is at present engaging the attention of every state association in the country, and which should interest the members of every county society. A clear understanding of what I am about to lay before you is of vital importance, for, without that understanding, you cannot appreciate the importance of active and hearty cooperation with the men you see fit to place in control of your affairs. If you will but give attention to the facts that I am about to recite, it will not be long before we can meet and thrash out honest differences of opinion fully and freely, and each one of us can fight for what seems to him to be in the interest of the association without the fear of giving comfort to the association's enemies. I refer to the skilfully planned warfare conducted by the stealthy foes of organized medicine, in which are employed the best efforts of many shrewd and experienced business men with unlimited financial backing, into which have been drawn, by one means or another, some through interested motives, some through honest misunderstanding, many of the most brilliant minds in the profession. An understanding of the nature of this campaign waged against the very existence of the Texas State Association and all other state associations will serve the double purpose of explaining why our friends are unwilling to engage in a fight to bring about changes and reforms that seem to them desirable, while confronted with the fear that their names and influences may be used by our foes to assist in poisoning the minds of the public against organized medicine, and, at the same time, will make plain and easy to understand the animus back of the ceaseless tirade of abuse to which every state journal editor, every trustee, officer and committeeman of every association and every house of delegates is treated. You will, then, understand why the Post-Office Department is besieged with demands that second-class mailing privileges be denied the state journals.

To begin with, you no doubt already know that all of the officers of all the state associations are treated to the same kind of abuse month in and month out, and that when the tactics of the enemy change in one state they soon change in other states. You know that the ammunition used against the profession in one state is used all over again in the other states.

You must know, then, that for all this there is a reason. The reason, my friends, is not far to seek:

1. Organized medicine is responsible for the Council on Pharmacy and Chemistry of the American Medical Association, with the resulting exposures of fraud and deceit, not only on the part of the low nostrums advertised in the cheap part of the lay press, but on the part of many, if not most, of our so-called manufacturing chemists, who, unhampered by any check and considering only the dollars to be earned, have for years been exploiting the profession and through the profession the public. The owners of the millions of dollars invested in the proprietary and "patent-medicine" business could not be expected to submit tamely to exposures which place in jeopardy their enormous business interests. They have not submitted tamely; on the contrary, they have by every means known to the shrewd commercial interests sought to destroy the system of organization which makes possible a continuance of these exposures. With this thought in mind, read the bitter attacks on your state association, other state associations and on the American Medical Association.

2. Dozens of medical journals which depend for their support and often their very existence on the protection of the interests that supply the medical profession with antikamnia, and the long list of less conspicuous proprietaries carrying space in medical publications, are assisting in the campaign against the profession to which their owners belong. The editors and proprietors of many of these journals are men of ability, men of standing in the profession, who under ordinary circumstances do not hesitate to wage war against fraud and deceit. According to ordinary business standards, they are not in any sense dishonorable men; journalism with them is a business just as selling groceries is a business. They do not pretend to endorse the claims of the proprietaries advertised in their pages. Their advertising space is for rent; they take the position that their space is for rent just as a room in a hotel is for rent and that they are no more compelled to vouch for the honesty of the claims made by advertisers than are hotel proprietors compelled to vouch for the uprightness of their guests. We do not complain of their use of advertising space in any manner they may see fit, but that they insist on regarding the official organ of the state association, which is used for the purpose of an interchange of ideas between our members and for conducting the association business, in the light of a rival engaged in a private enterprise who adopts unfair methods of competition. The fight is between the private journal interests, which are business enterprises on the one hand, and the association on the other, because this body finds it necessary to publish a journal as a part of a scheme for carrying on its benevolent purposes, and which representing organized medicine finds it necessary to wage war on the commercial interests that are imposing on the medical profession, and through the profession on the public.

It is unfortunate that the association cannot conduct a campaign of education which happens to affect the manufacturer of proprietary medicines without treading on the toes of our friends who are engaged in medical journalism as a private business.

3. The influence of organized medicine is responsible for the campaign of education which resulted in the enactment of the national pure food and drug law and has assisted in its enforcement. Here again great wealth is forced into a fight against the medical profession. The enemies of the pure food and drug law find it expedient to join our other enemies.

4. Low-grade medical schools, and all the many powerful interests linked with their interests, are fighting organized medicine because of the successful fight that the profession is making to elevate medical college standards. This, of course, means the ultimate elimination of low-grade schools and such a policy is naturally very objectionable to the doctors who run medical schools for their own interests rather than in the interest of the public and the profession.

5. All of the "isms" and "pathies" in medicine, and all of the freak cults, are slowly but surely being eliminated by the adoption of uniform standards for all who seek license to practice medicine, and by laws which so broadly define medicine as to include all who treat the sick for a consideration. As long as freak schools and sectarians are allowed to assume the rôle of martyrs, persecuted by the medical profession for righteousness' sake, and can secure laws under which they may legally define the practice of medicine to suit themselves and can set up their own standards, they will continue to multiply and prosper and new "treatments" with coin enticing names will rise up for the benefit of the crank, the bunco man, and the doctor who cannot make a living at legitimate practice.

6. Organized medicine in Texas is responsible for a law which not only makes it a crime for an ignorant person to assume the responsibility of treating the sick for any ailment, mental or physical, by any method or system whatever, but also makes it a crime to be guilty of "grossly unprofessional or dishonorable conduct of a character likely to deceive or defraud the public," and the penalty is a fine, a jail sentence, and a loss of license. This clause of the practice act was recently invoked in the case of a notorious advertising quack who was tried at San Antonio and had his license revoked. Ever since then he has devoted most of his time in denouncing the medical "trust" and has declared war to the death of the octopus. He delivers a free lecture from every convenient platform and offers his services to all who would kill the great trust dragon which has seen fit to interfere with his right to rob the thin purses of the poor and the ignorant. This recent addition to the anti-organizing crusaders has amassed a snug fortune by taking large fees, often more than $100 at a time, from unfortunates whom he has been able to attract to his lair with the assistance of the press by causing them to pass, with the aid of an olive oil mixture, soap concretions, which his victims are made to believe are gall-stones.

7. Add to these, the usual complement of disgruntled brethren who for one reason or another are always "agin the government" on general principles, the man who thinks that all the reforms in the world are not worth the two dollars a year he is required to pay for membership fee; also the man who does not want to belong to the association and who is against it because it is not what it used to be when he was a boy.

With such an army arrayed against the profession, and in the face of the fact that the men who are elected to manage the association affairs do so at great personal sacrifice without any hope of personal reward, the well-wisher of the association is, as a rule, loath even to suggest reforms which, in his judgment, are needed, for fear of discouraging the men in control of the association affairs and giving comfort to the enemy. The allies are ever on the lookout for recruits. At the earliest signs of dissatisfaction with any of the association officers, or of its policies, the mind-poisoning squad begins to spread the glad tidings that something has gone wrong with the association; that a big split is about to take place; that the sore-head is about to come into his own; that perhaps somebody has been grafting from that two dollars collected for dues. Then the independent journal begins to beat the tom-tom, the proprietary medicine interests commence to delve into the past of the men who have been exposing their frauds. The magnetic healer begins to work on his dynamo and the man who does not like the editor anyhow takes down his snickersnee, and the whole army marches out to engage in the battle.

The profession as a whole understands the nature of this warfare. Never before has the profession been so united as it is to-day. Never have the parasites which feed on the doctor and make him the middle man for reaching the public with dishonest and misbranded proprietary medicines been at so great a disadvantage as now. Never before have the doctors so clearly understood the Dr. Jekyll and Mr. Hyde part played by our large manufacturing concerns. Never have the public been so willing to assist in the enactment and enforcement of laws in the interest of public health. Never have the "schools" of medicine, the quacks and the medical bunco-steerers had so many things to worry about.

The end of this great fight against the medical profession is in sight. The great interests whose business it is to manufacture medicines are adjusting their affairs so as to meet the honest requirements of the Council on Pharmacy and Chemistry and in a short time they will have no reason to continue a fight against honesty in the scale of proprietaries. Hight standards of requirements are eliminating the low-grade medical schools and putting out of business the "isms" and "pathies" in medicine. The public is being rapidly educated and assisting in this great work. The independent medical journals that are worthy to live because of real merit will continue to prosper. Those that cannot live without the support of dishonest advertising houses must go out of business or else improve themselves so that they will be worthy to live.

Your understanding of the nature of the fight that has been waged against the profession will forever put an end to that fight, and your active interest in association affairs will make possible the accomplishment to the fullest extent of the purposes for which the organization exists.

Societies Endorse Owen Bill

The following organizations have passed resolutions endorsing the principles of the Owen bill: Santa Clara (Cal.) County Medical Society, Humboldt County (Cal.) Medical Society, Woodbury County (Ia.) Medical Society, Buncombe County (N. C.) Medical Society, State Medical Association of Texas, Oklahoma State Medical Association, Lamar County (Tex.) Medical Society, Georgia State Medical Association, St. Joseph-Buchanan-Andrew Counties (Mo.) Medical Society, Portland City and County (Ore.) Medical Society, Medical and Chirurgical Faculty of Maryland, Denison County (Tex.) Medical Society, Cincinnati Civic League, Chamber of Commerce, Tacoma, Wash., Board of Trade, Tacoma, Wash., Tacoma Commercial Club, Tacoma, Wash., Mississippi State Department of Health, Madison County (Wis.) Medical Society, Missouri Association for the Relief and Control of Tuberculosis, Rock Island (Ill.) County Medical Society, Essex North District (Mass.) Medical Society, Southwestern Kentucky Medical Association, Wright County (Ia.) Medical Society, Washington County (Pa.) Medical Society, Medical Society of the County of Kings (N. Y.), Sheridan, Mont., Board of Trade, Robertson County (Tenn.) Medical Society, Lorain, O., Chamber of Commerce and Board of Health, Lorain (O.) Medical Society, Huntingdon County (Pa.) Medical Society, Medical Society of the County of Cortland (N. Y.), Cortland Board of Trade, Southeastern New Mexico Medical Association, Missouri State Medical Association, School Improvement Association of Helena, Ark., Houston-Fillmore Counties (Minn.) Medicolegal

Rights Between Carrier and Person Requiring Medical Attention

The Supreme Judicial Court of Massachusetts says that the case of Connors vs. Cunard Steamship Company (90 N. E. R. 601) presented an important question not directly decided in any case which has come to the court's attention. The suit was brought by Alice Connors, as administratrix of Margaret Connors, deceased. The two sisters had embarked on the Ivernia, having a ticket entitling them to a second cabin passage from Boston to Queenstown (or Liverpool). But Margaret undressed and went to bed before the vessel cast off from the wharf, which was reported to the ship's surgeon, who went to her room, felt her pulse, looked at her tongue and asked what was the matter. Thereupon Alice handed him a letter from a physician, addressed to the ship surgeon, saying: "May I explain to you a most sad case which will be under your care during this crossing? The patient herself has no idea of the nature of her trouble, so will you kindly make light of anything ocurring and give us your aid in concealing facts? This note will be handed to you by her sister, who knows all. She has endothelioma of uterus too advanced for more than curetting and cautery, which I did February 13 [letter dated 27th]. Unfortunately this is her week to expect menstruation, but I trust it will give you no special trouble. She will be supplied with creolin for douches and codelia suppos. (ov grs. 1ss) for pain if needed. May I suggest an early vaginal pack should the loss of blood pass the normal that strength may be saved until she reaches home?" After reading the letter, the surgeon left the room and gave directions that the woman should not be allowed to proceed on the voyage. The court is of the opinion that this was justifiable, under the circumstances.

The general rule that a common carrier is bound to accept anybody and everybody who presents himself for transportation and pays the regular fare, the court says, has its limitations. A common carrier is bound to care for all who have become its passengers. For that reason not only is it not bound to accept, but it is under obligation to refuse to accept as a passenger an insane person without a proper attendant or attendants, or one who has smallpox. It was held in cases cited that the justification was made out if the carrier had reasonable cause to suppose, and did suppose, that the safety or convenience of other passengers would be endangered by the person in question, and that it was not necessary to wait to see if the person believed, and with reason, to be afflicted with an infectious disease or so insane, drunk, or sick as to be likely to interfere with the safety or the convenience or both of other passengers, was or was not in fact in the condition he appeared to be in.

This doctrine was admitted by council in this case, but with the contention that the right of the carrier to exclude a person who wishes to become a passenger is confined to those cases where the safety or convenience of other passengers is endangered, or thought to be so, and that the mere fact that a person is afflicted with an internal disease will not justify a carrier in refusing to accept him as a passenger if he offers to pay his regular fare. However, the court thinks it plain that the right to exclude is not confined to cases where the safety or convenience of other passengers is endangered, or thought to be exdangered.

The question of accepting as a passenger a person in need of medical attention is a more serious one in case of a carrier by water than in case the proposed transportation is on land. Hospitals abound on shore, and even where there are no hospitals physicians and surgeons can be found at different stopping places to whose care the traveler in need of medical attendance can be confided. But in case a person in need of medical attendance is taken as a passenger on a sea voyage she must be cared for until the voyage is at an end, and if she is not accompanied by her own physician it might well be held that the responsibility of caring for her had been assumed by the carrier.

The court is of opinion that a common carrier is bound to take as passengers all who offer themselves, ill or well, provided the carrier can furnish the necessary accommodations and the passenger is willing to pay for what he demands. But where a person who is ill presents herself to a common carrier for transportation by water it is her duty to state the fact that she is ill and make special arrangements for her transportation as a person in need of medical attention.

The case of a person requiring medical attendance does not come within the same class as the cases (put in some of the opinions) where a very old or a very young person is alighting from a car and for that or any other reason requires more time than a person in good health and not under a disability. Those persons and persons laboring under other difficulties are included in persons fit to travel. What was to be considered here was the case of one not fit to travel without medical attention. Had notice been given to the defendant corporation of the condition of this woman when her ticket was bought for her the question of what care her physical condition was likely to demand and how and by whom it was to be provided could have been taken up with deliberation and some special arrangement made for the necessary extra care and the amount to be paid to the company if it was arranged that the extra care was to be furnished by it.

The court is of the opinion that the presentation of the letter was a representation by the woman that she needed medical attention during the voyage and looked to the company to supply it. If after the visit which the ship's surgeon paid to her while she was lying in bed in her rooms she had not been put ashore there would have been a serious question whether the company had not assumed the responsibility of giving her proper medical care during the voyage.

A ship's surgeon seems to have been aboard the Ivernia in compliance with the English statute which requires every passenger ship to carry a duly qualified medical practitioner whenever the number of persons on board exceeds 300. It may be assumed that a passenger who falls ill during the voyage can call on the "medical practitioner" for medical attention. But neither the statute, nor the presence on the Ivernia of a "medical practitioner" in compliance with that act, changes the right of a common carrier by water not to receive as an ordinary passenger a person in need of medical atention. In the court's opinion a carrier has that right.

Points from Decision in Favor of Physician Charged with Assault with Intent to Commit Rape

The Supreme Court of Iowa says, among other things, in its decision in the case of State vs. Sells, which it characterizes as unusual in many of its features, that under the statutes of that state, to sustain a verdict of guilty the testimony of the prosecuting witness must be corroborated by other evidence from some other and independent source, tending to connect the defendant with the commission of the offense. But when the offense was charged to have been committed in his own home or office where he had an undoubted right to be, and in a room or place where he was accustomed to meet visitors or transact business with patrons on one of whom the assault was charged to have been made, no possible sinister significance could be given to the mere fact of his presence there, and the corroboration which would satisfy the requirement of the law in such case ought to be more direct and satisfactory than would be held sufficient were he a trespasser or an intruder.

Taking the tendency of the evidence on both sides to show that, at the time of the visit when the commission of the offense was charged, the prosecutrix became for a time unconscious or delirious, with other circumstances, it seems not an unreasonable theory that she was the victim of an hallucination by which the vagaries of an abnormal and distorted imagination had been impressed on her mind as the memory of an actual experience.

It is unfortunately true that such an accusation, however false, especially when made against a professional man whose business calls him into frequent dealing and association with women, is always injurious and often ruinous to him against whom it is directed. So true is this that physicians of the very highest character have sometimes been led to submit to imposition and to compromise with their accusers rather than take the chances of irretrievable injury from public attack on their personal or professional reputation. That the defendant showed signs of anxiety over the story imperiling his good name and should seek the young woman and her friends, and, while asserting his innocence, ask if there were not some way in which the matter could be fixed and the scandal suppressed, might not argue very well for his judgment, but it was just as consistent with the theory of innocence as with that of guilt.

It should also be said in this defendant's behalf that, so far at least as appeared from the surface, he had taken reasonable precaution to protect both himself and his female patients from liability to scandal of this nature. His profession is an honorable one, and one which brings its votaries into the closest and most intimate relations with their clientage. That he had established a hospital in which to receive and treat patients was certainly not to his discredit. He had employed a woman nurse as an attendant in the hospital who had access to its various rooms and departments, and assisted him in the care and treatment of those coming to employ his services. More than this could hardly be expected of a physician practicing in a small country town. Whether both he and the nurse were present at the visits of the prosecutrix was a disputed question, but the arrangement of the building, the employment of the nurse therein, her general duties about the premises, the coming every day of from ten to twenty or more patients who had entrance to the building and were treated therein reduced the probability that rape or assault with such intent could have been committed therein in the manner claimed by the state.

Ordinarily where a case is to be remanded for a second trial this court does not express any opinion on the testimony, but it suggests in this case that, if the state finds itself unable to offer other or additional or further proof in support of the indictment, it will be advisable for the prosecution to enter a dismissal.

29 Sewerage and Water Supply. J. C. Boehm, St. Cloud, Minn.

27. **Metabolism and Modern Treatment of Diabetes.**—Bissell emphasizes that a patient with diabetes requires exactly the same amount of food that is required by a normal individual under the same conditions, usually about 35 to 40 calories per kilogram. In no case should a sudden and radical change be made from one diet to another, but, on the contrary, one should proceed carefully and determine as nearly as possible the tolerance of the patient for carbohydrates. This not only makes it possible to properly classify each case, but in great measure, makes the prognosis. The procedure followed by Bissell is to add to the standard diet 100 gm. of wheat bread and see what happens. He says that if less than 50 gm. of sugar appears in the urine, withdraw carbohydrates and see if sugar disappears. If more than 50 gm. appears, do not withdraw carbohydrates from the diet, but give on the second day 75.0 wheat bread, on the third day 50.0, and on the fourth 25.0. Then if no diacetic acid or acetone has appeared, withdraw entirely. If sugar disappears from the urine we know we are dealing with a mild form of diabetes. If, on the other hand, sugar persists in the urine on a carbohydrate-free diet but disappears when albumen is given in as large a quantity as 600 grams per day, the case is one of medium severity. The severest type of case is manifested by the persistence of sugar even under starvation treatment.

Doubtless an inheritance from an earlier conception of this disease, the practice still prevails in many quarters of placing every diabetic on the standard carbohydrate-free diet regardless of his power of sugar combustion or tissue requirement. The patient either frankly rebels, surreptitiously resorts to the food which his tissues crave, commits suicide, or develops acidosis.

It is the essential object of Bissell's paper to emphasize the necessity of determining the boundary of sugar assimilation in each case before beginning treatment. Having determined the point and the caloric requirement of the individual the selection of a diet is quite simple, if certain changes are borne in mind.

36. **Dysmenorrhea in Nulliparous Women.**—The statistics for this paper have been drawn from 73 cases operated on during the last eleven years. Of these 73 cases Norris and Barnard have been able to trace 40. Cured, 18, or 45 per cent.; improved or temporarily cured, 11, or 27.5 per cent.; not improved, 11, or 27.5 per cent. The results of the various operations are as follows: Dilatation and curettage performed 28 times: Cured, 11, or 39.28 per cent.; improved or temporarily cured, 11, or 39.28 per cent.; not improved, 6, or 21.42 per cent. Dilatation and curettage and Wylie's drain performed nine times: Cured, 6, or 66.66 per cent.; improved or temporarily cured, 1, or 11.11 per cent.; not improved, 2, or 22.22 per cent. Dudley's operation performed once: cured, none; improved or temporarily cured, none; not improved, 1, or 100 per cent. Dudley's operation combined with Wylie's drain performed four times: Cured, 2, or 50 per cent. In two of the 40 cases no record as to the character of the dysmenorrhea was obtainable. The remaining 38 cases, arranged according to the character of the dysmenorrhea, without regard to the operation performed, give the following results:

Ten cases of digestive dysmenorrhea: cured, none; improved or temporarily cured, 2, or 20 per cent.; not improved, 8, or 80 per cent. Eleven cases of spasmatic or expulsive dysmenorrhea: cured, 9, or 81.81 per cent.; improved or temporarily cured, 2, or 18.18 per cent.; not improved, none. Seven cases in which the symptoms were a combination of the spasmatic and congestive types: cured, 3, or 42.85 per cent.; improved or temporarily cured, 1, or 14.28 per cent.; not improved, 3, or 42.85 per cent.

These tables are most striking. When we find that in one type of dysmenorrhea we can cure by operation 81 per cent., while in another we can obtain no absolute cure, and only 20 per cent. of improvements, the necessity of recognizing the character of the dysmenorrhea becomes apparent. Careful diagnosis as to the etiologic factor producing the dysmenorrhea is, in the authors' opinion, the key to the success in the treatment of this condition. Of the above 40 cases 20 were married, 14 had been married for two years without issue. Of these 14 previously sterile cases, 5, or 35.71 per cent., became pregnant within one year following the operation. Two cases of dilatation and curettage had the operation repeated and both were temporarily improved; one patient had a hysterectomy performed and was cured; one had a bilateral oöphorectomy performed and was cured; one case of an unmarried girl who had a dilatation and curettage performed without any relief, about a year after the operation married and became pregnant. The dysmenorrhea was cured by labor. One case was temporarily improved by dilatation and curettage; the menopause appeared four months after operation.

52. **Pancreatic Cyst.**—The patient had noticed a lump in the abdomen, which did not give rise to any symptoms until five days before admission, when she was seized with a sudden sharp colicky pain in the abdomen, in the region of the mass. This lasted a short time, then subsided, and returned after a day and a half. Examination showed a large slightly movable, spherical tumor, situated high in the abdominal cavity and not involving the uterus. Urine and blood examinations negative. The tumor was supposed to be an ovarian cyst on a long pedicle, which had twisted, causing the pain. On opening the abdomen, the tumor was found to be in the lesser peritoneal cavity, and proved to be a large cyst about the size of a grape fruit, free from adhesions except at its pedicle, which consisted of the head of the pancreas. The cyst was dissected out, it being necessary to cut through the pancreatic tissue of the pedicle. Every possible bleeding point was ligated with catgut, the opening into the lesser peritoneal cavity was closed with catgut and the abdomen closed with drainage. Convalescence was rapid, afebrile, and uncomplicated, patient leaving the hospital two and a half weeks after operation. There were no digestive disturbances or abnormalities in bowel action at any time.

The noteworthy features in this case are the extremely successful result following the uncommon operation of total extirpation; the proof of its being true pancreatic cyst by the presence of pancreatic tissue in the wall of the cyst; and the presence of large quantities of mucin and two enzymes—diastatic and emulsifying—in the cystic contents.

66. **Relation of Trauma to Cancer.**—From a general observation of cases and from a comparative study of discordant statistics Phelps concludes that cancer is primarily dependent on a cause which is congenital, is hereditary in a certain proportion of cases, and is as inexplicable as the force which determines *ab ovo* the future sex and peculiarities of the individual. Its development is favored by various indeterminate and nonessential conditions and is not due to trauma unless oft repeated. Its proximate cause is as yet entirely unknown, and

its future determination will depend on the possible verification of a parasitic infection. These propositions are supported by the frequent occurrence of the disease in persons who are still in early or middle life, without hereditary predisposition, and in absolutely normal and mental equilibrium; and this in the absence of any of the accepted favoring condition.

67. **Skeletal Carcinomatosis.**—In Hawley's case an accident (spontaneous fracture), not frequently occurring in carcinoma of bone, led to the discovery of bone disease, and the history of breast cancer gave a clue to its probable nature. About one year after amputation for cancer, the patient's left leg gave way in the right thigh. Swelling about the hip followed the injury to both legs. Further skeletal examination revealed a moderate total lateral curvature of the spine to the right; tenderness over the third and fourth lumbar vertebræ, and over the seventh and eighth ribs on left side, and under the pressure of the examining finger the seventh rib caved in with the feeling of crepitus. Radiographs showed a fracture of the left femur about 4 inches below the trochanter, with considerable callus formation, overriding and angulation, also irregular areas of osteoporosis in the shaft and neck. The radiograph of the right hip showed a fracture just below the trochanter with the fragments united at a right angle; also honeycombing of the shaft, neck and trochanter. Other exposures made revealed similar areas of softening in both fibulæ and two ribs.

69. **Pathology of the Gall-Bladder.**—As the result of clinical and pathologic study of 365 cases of cholecystectomy, MacCarty concludes that the lesions in the gall-bladder are not definite entities, but degrees in a process of reaction to irritants. He divides these lesions into eight groups as follows: (1) *Cholecystitis catarrhalis acuta:* 65 uncomplicated cases and 90 cases complicated by other stages. Forty-five (69 per cent.) of the uncomplicated cases were associated with gall-stones; (2) *cholecystitis catarrhalis chronica:* 39 uncomplicated cases and 39 cases associated with other types of inflammatory reaction, 30 (76 per cent.) of the uncomplicated cases contained stones; (3) *cholecystitis catarrhalis papillomatosa:* In this group there was only one specimen. One of the villi was enlarged and appeared as a papilloma. The condition was associated with stones and an acute catarrhal reaction in the mucosa; (4) *cholecystitis papillomatosa malignum:* This type does not occur in this series because the cases seen were studied at exploration of inoperable cases; (5) *cholecystitis catarrhalis carcinomatosa:* Three cases of *cholecystitis catarrhalis chronica* were complicated by carcinoma; (6) *cholecystitis chronica:* 78 uncomplicated and 64 complicated cases; of the uncomplicated, 73 (93 per cent.) were associated with stones; (7) *cholecystitis chronica cystica:* 76 cases; (8) *cholecystitis purulenta necrotica:* 33 cases. Pericholecystitis acuta or chronica is considered a sequel of any of the above mentioned degrees of inflammation.

Two hundred and fifty-two, or 67 per cent. of the 365 cases were associated with gall-stones, which varied in shape, size and composition, all of which properties bore no apparent relation to the character of the lesion in the gall-bladder. Of the chronic catarrhal gall-bladders, 76 per cent. were associated with stones. In the more advanced cases of chronic inflammation, in the cases in which practically all of the mucosa was destroyed, the percentage was 93. From these figures it would seem that the occurrence of gall-stones bore a marked relation to the extent of the lesion and that the early acute catarrhal conditions do not necessarily occur associated with stones. MacCarty urges that the gall-bladder, liver, duodenum, pancreas and stomach are embryologically, anatomically, physiologically and pathologically closely related and should be considered a gastro-duodeno-hepatico-pancreatic physiologic system.

72. **Operation for Umbilical Hernia.**—On account of the accumulated fat in the abdomen the tension in these cases is sometimes considerable, and favors return of the hernia. To overcome this Kelly makes an incision from the right and left margins of the hernial opening all the way across and through the strong fibrous sheaths of the recti, then detaching and raising the sheaths from the recti above and below for 2 or 3 cm. The hernial sac is then freed from the rest of the tissue. It is opened and any adherent omentum present is removed. If the intestines are adherent they are carefully dissected free, and replaced in the abdominal cavity. The peritoneum is next sewn together with catgut. Next sew the free margin of the lower under the upper flap from side to side with four to six interrupted silk sutures, using if needs be, catgut between them. If the transrectal incision is angled a little upward and the overlapping of the recti is well done, there may be little tension; there is always a greatly diminished tension in the overlapping at the ring itself. The free overhanging margin of the upper flap is now sewed by a continuous catgut suture to the fibrous tissues and the supporting part of the operation is completed.

82. **Pseudodiphtheria and Diphtheria Bacillus.**—From a careful study of the literature, and from an extended series of experiments, Clark believes himself justified in saying that the pseudodiphtheria bacillus or *B. hofmanni* belongs to a different species from the true Klebs-Löffler bacillus. Doubtless both organisms belong to the same groups and came from common ancestors, but the differences seem to be sufficiently constant to place them in separate species.

83. **Plague Infection in a Brush Rat.**—The fact is now established, says McCoy, that these animals may have plague, which adds another factor to the already perplexing problem of the transmission of plague among the rodents of the Pacific Coast. Fortunately, the brush-rat is not sought for its flesh, as is the ground squirrel, nor does it ordinarily build its nest near human habitations as do the domestic rats.

85. **Bacteria in Bottled Milk.**—Torrey and Rahe found that the upper two ounces of the cream of fresh bottled milk of fair quality contain on the average of 50 to 100 per cent. more bacteria than an equal amount of the lower cream. In older and more grossly contaminated milk the lower cream may embody as many as Hess has suggested; there generally results a reduction of from 30 to 50 per cent. in the bacterial count. The dominant controlling factor in the primary disposition of bacteria in a milk bottle is the upward "rafting" activity of the fat globules. A higher percentage of bacteria are brought to the surface layers in a milk rich in cream than one poor in that substance. At ice-box temperature the rate of increase of bacteria in the cream and that in the skim milk are practically identical. As the temperature is elevated the rate of multiplication in the skim milk outstrips that of the cream until at 30 C. it may be many times as rapid. In certain samples of rather highly contaminated milk the abrupt

change in the temperature of the environment from 5 C. to 30 C. caused a striking bacteriolysis in both the cream and the skim milk. This was probably an expression of bacterial antagonism. The sediment portion of the average bottle of fresh milk contains frequently fewer bacteria than any other region of the fluid. A marked excess of bacteria in the sediment indicates that the milk is old or that it has been kept in a warm place.

86. This paper covers similar ground to that of the same author published in THE JOURNAL, Feb. 26, 1910, p. 704.

88. **Chronic Pneumococcus Endocarditis.**—The points that in Rosenow's opinion seem to merit specific emphasis are the following: In chronic pneumococcus endocarditis the serum has no pneumococcidal power by itself. The phagocytic power of the patient's blood is usually a better index of the actual conditions than the opsonic power of the serum determined with normal leucocytes and even with patient's leucocytes. The destructive power of the patient's blood as compared with that of normal blood corresponds well with the clinical conditions. Hence less reliance should be placed on the results of the opsonin determinations in which no account is taken of the fate of the ingested cocci. The phagocytes in chronic infectious endocarditis show greater variation in their own serum than in normal serum. Variations in the opsonic power of the sternum sometimes occur independently of variations in the phagocytic and destructive power of the leucocytes, but the variations on the part of the leucocytes is always dependent on changes in the serum. While the chief action of serum in phagocytic mixtures is on the bacteria, there is no question, from the evidence at hand, but that the serum also exerts a definite and sometimes a striking influence on the leucocytes. Intraleucocytic destruction is dependent on a substance or property always present in normal serum and in normal leucocytes after treatment with normal serum, but frequently absent in the serum and leucocytes in chronic cases of endocarditis. At times the patient's serum is not only lacking in this substance, but contains another substance which seems to neutralize that in normal serum. This substance is not taken up by the bacteria but the opsonin or some other substance contained in washed sensitized pneumococci is necessary to activate it, because the cocci, which have undergone spontaneous phagocytosis fail to show digestion. Phagocytosis alone, even though marked, does not seem to injure the leucocytes in any way. The bacteria isolated from the cases shown appear to be modified pneumococci and prolonged cultivation in normal serum not only renders them largely resistant to phagocytosis, but makes them also resistant to intraleucocytic digestion. Both these properties are promptly lost in artificial media.

92. **Potency of Antidiphtheritic Serum.**—The average yearly loss in potency of diphtheria antitoxin is about 20 per cent.; at 15 C., about 10 per cent.; and 5 C., about 6 per cent., although in some instances these percentages may be much increased. As a result of this work, there appears to be but little difference in the keeping qualities of untreated sera and sera concentrated by the Gibson process. Diphtheria antitoxin to be placed on the market and there kept under unknown conditions as regards temperature should not be labeled with a return date longer than two years for decrease in potency; in addition, when the serum is sold in syringes with an absorbable piston an excess should be added for this loss. Dried diphtheria antitoxin kept in the dark at 5 C. retains its potency practically unimpaired for at least $5\frac{1}{2}$ years. The lack of confidence in the therapeutic properties of old sera is without basis, as such sera, unit for unit, are as potent as new sera. The protective value of diphtheria antitoxin is in exact accord with its unit value, and is independent of the volume of the serum or other properties in the serum.

7 Causes of Absorption of Oxygen by the Lungs. C. C. Douglas and J. S. Haldane.
8 Auscultatory Friction. H. H. Brown.

2. **Von Pirquet's Tuberculin Reaction.**—The reaction was tried by Mills on 48 children who had been carefully examined without any evidence of tuberculous disease being detected. In every case the reaction was negative. Of cases known to be tuberculous there are 21 in Mills' series. Of these, 19 gave a positive reaction. Two cases gave no reaction; they were: tuberculous peritonitis, tuberculous hydrocele of the tunica vaginalis. Of cases clinically diagnosed as tuberculous there were 43. Thirty-four gave a positive reaction, 9 gave a negative reaction. Of these, 8 eventually proved to be almost certainly not tuberculous. The remaining case, one of spinal caries, is one of the 4 cases in his series in which the reaction was misleading. Of cases clinically doubtful there were 11. Three of these gave a positive reaction; 8 cases gave a negative reaction. Thus of a total of 123 cases the reaction was misleading in 4 only. Two of these were tuberculous peritonitis, one was spinal caries, and one was lymphadenoma, in which the reaction was positive. Mills also found that a previous injection of tuberculin will not produce a reaction in a healthy patient, while an initial injection of tuberculin modifies the type of the reaction in a tuberculous case. The type returns to normal in about a week. Bovine tuberculin behaves in an exactly similar manner to ordinary human tuberculin when used for the reaction. The reaction to bovine tuberculin was similarly modified in type by a subcutaneous injection of human tuberculin.

3. **The Tuberculin Skin Reaction.**—Bride applied the test in 92 cases. He came to the conclusion that the test is of great help in the early diagnosis of pulmonary tuberculosis and in its distinction from unresolved pneumonia and chronic bronchitis, in the differential diagnosis between enteric fever and abdominal tuberculosis, in the early diagnosis of abdominal tuberculosis, and also in the diagnosis of the cause of pleuritic effusions. It is not of much help in cases of tuberculous meningitis, tuberculosis where some acute infectious disease accompanies it, and in tuberculosis associated with much pyrexia.

6. **Calcium Permanganate in Plumbism.**—Stephens found calcium permanganate to be of value in the treatment of plumbism, giving ¼ grain (0.015 gm.) three times a day.

15 The Occurrence of Acetonuria in Cases of Infectious Diseases. A. Harris.
16 Case of Lymphatism. L. P. Burt and J. R. Collins.

14. **Delivery in Contracted Pelves.**—Tweedy sums up his views on the treatment of contracted pelves as follows: 1. Induction of premature labor is never advisable. 2. Perforation is not permissible unless the child is dead. 3. Turning should never be employed as a treatment for contracted pelvis, but may still be performed for complications of labor, such as prolapse of the cord when associated with contractions of the first and second degree. 4. In the greater degrees of contraction time should not be wasted in an endeavor to obtain natural delivery. 5. On the other hand, in the lesser degrees ample time should be given the woman to enable her to deliver herself if possible. Eight or ten hours may be necessary for the molding of the head, and interference should not be considered until there are evidences of fetal or maternal distress. Once fetal symptoms of distress are manifested there should be no delay in delivery. Walcher's position should not be forgotten as an aid to fixation of the head; 6, high forceps should never be applied until all arrangements are perfected for an operation to enlarge the pelvis. It is, in his opinion, a pity to proceed to the latter expedient until forceps have been tried tentatively. It must be confessed they occasionally accomplish their purposes under the most unexpected circumstances. Finally, in these, as in all other obstetric operations, the best results cannot possibly be obtained if rubber gloves are not worn.

19. **After-results of Abdominal Operations.**—According to Giles the removal of both ovaries and tubes has no marked effect on the subsequent health, for 78 per cent. of the patients were in very good health afterward, and a further 13 per cent., though suffering in different ways, were better than before the operation, making in all 91 per cent. who were quite well, or at least improved. The condition of the general health is even better than it is after unilateral salpingo-oöphorectomy. The likelihood of later trouble developing in connection with the uterus when the organ is left is relatively small, as such an occurrence took place in only 7 cases out of 105. It is therefore worth while leaving the uterus in all cases where it appears to be healthy. The removal of the uterus appears to increase the immediate risk of the operation in inflammatory cases. Menstruation continues after these operations in about 40 per cent. of the cases, the proportion being largest in cases where the operation was done for inflammatory disease. When menstruation persisted after ovariotomy for tumors, it was mostly in cases where the tumors were parovarian or intraligamentary. The inference is that some portion of ovarian tissue has remained behind in these cases.

20. **The Ureter in Cancer of the Cervix Uteri.**—Leitch found that involvement of the ureter is the commonest occurrence in post-mortem examinations of cancer of the uterus. It can be demonstrated also in operable cases. This involvement consists in the production of stricture frequently, (a), by contraction of growth in the surrounding parametrium; (b), by invasion of the ureter wall; and sometimes, (c), by fibrosis in the parametrium, due either to chronic inflammation or to the reaction to cancer cells which have disappeared locally. The ureteral wall may be invaded by cancer directly from the surroundings, the invasion being sometimes evident on naked eye examinations; at other times, even when extreme, demonstrable only by the microscope. Lymphatic permeation of the ureter does occur, and the lymphatic vessels of the ureter and parametrium probably communicate. The nature of the surrounding tissue in the parametrium, the open texture, the proximity of the principal lymphatic vessels from the uterus, the danger of invasion and the peculiarity of the blood supply render resection of the parametrial portion of the ureter advisable when the parametrium is invaded.

33 Functional Disturbances Dependent on the Specific Muscular Systems of the Heart. E. Hering.

31. **Anemia and Leucolytic Processes Following Roentgen-Ray Exposures in Leukemia.**—The authors consider that the two cases reported demonstrate that Roentgen-ray treatment of leukemia induces both direct and indirect leucolysis; the latter is the work of a leucolytic ferment which seems to be produced in some way under the influence of the rays, and which prolongs the leucolytic action. The red corpuscles also feel the effect of the rays to some extent, so that the blood picture comes to approximate that of pernicious anemia. There is thus always the possible peril with radiotherapy of leukemia that the chronic myelogenous leukemia may become transformed into an acute phase by the development of this corpuscle-disintegrating ferment. The cases further emphasize, they state, the necessity for cautious technic in radiotherapy, with long intervals, especially when the patient reacts promptly and energetically to the exposures.

39. **Iodin Method of Surgical Sterilization.**—Bérard and Chattot have tested tincture of iodin in treatment of accidental wounds and state that the results showed that it is fully able to sterilize the hands experimentally contaminated with ordinary accidental germs. In a number of emergency cases during the last 3 years, while the field of operation was being painted with the tincture, the surgeon poured the tincture pure or diluted with alcohol over his hands, letting them dry spontaneously before rubbing off the excess with an alcohol wad, omitting all preliminary scrubbing, but there were no infectious complications. The only drawback is that the hands are liable to chap if it is done several times during the day. In order to avoid this, when time permits, they scrub first and thoroughly dry the hands, then pour the tincture of iodin on the fingers, spreading it thence over the forearm. The whole sterilization is complete in from 5 to 7 minutes and they have never had excoriation result with this latter technic. A number of aseptic operations can be performed in turn without renewing the sterilization, merely washing the hands between with soap, water and alcohol for a few minutes. But this loses the main advantage of the Grossich technic, which is that the tincture of iodin alone enables the surgeon to operate safely in regions otherwise prone to infection.

May 11, No. 38, pp. 353-360

45 Influence of he Temperature of Deep-Lying (La diathermie.) A. Zimmerı

40. **Acute Thyroiditis and Cardiovascular Complications.**—Parisot has encountered four cases of this kind. In the first, the thyroiditis followed the subsidence of puerperal fever; in the second it developed six weeks after the onset of typhoid fever; in the third it occurred during convalescence from mumps in a man of 28. In all these cases the thyroiditis subsided under medical measures but in the fourth case the thyroiditis came on 26 days after the onset of a sharp but brief pneumonia from which the patient had entirely recovered. In this case the process in the thyroid progressed to suppuration, and the pneumococcus was found in the pus. In all the cases there was marked tachycardia without any connection with the temperature. This lack of connection with the fever, which might be severe, mild or entirely absent, was a striking feature of the cases and, when encountered, Parisot says, should suggest thyroiditis and compel search for signs of disturbance in that region. The tachycardia was sometimes aggravated by physical exertion and sometimes was accompanied by paroxysmal palpitation of the heart. Various vasomotor reactions were also noticed. The blood pressure was also at times abnormally low. Study of the cases has demonstrated that these cardiovascular symptoms were always connected with the phase of congestion in the gland; the inflammatory congestion induces hyperfunctioning and this is responsible for the cardiovascular complications. In conclusion, he compares his cases with a few similar ones on record, emphasizing the fact that these cardiovascular complications of acute thyroiditis may become associated with other symptoms to form an incomplete and transient exophthalmic goiter or may merge into the typical and permanent form.

41. **Experimental Dwarf Growth Induced by Tobacco Poisoning.**—Perrin and Richon systematically injected 19 young rabbits from three litters with an infusion of tobacco and found that it seemed to arrest the growth of the animals to a certain extent, both weight and size being considerably less than in the controls from the same litters. There was no tendency to rachitis or malformations, merely a lesser growth of all the tissues. After cessation of the injections the animals grew normally but never attained the size and weight of the controls.

42. **Physiologic Action of Quinin in Malaria.**—A diagram and several clinical charts illustrate the points emphasized by Tournade and Giraud, namely, that the dose of quinin should be given at the hour when the malaria germs are in the most vulnerable phase of their development, and that the dose should be large enough to act thoroughly on them all. If the dose is given when the plasmodia are in the prime of their vitality or are sheltered inside the blood corpuscles it has comparatively little effect on them, and if the dose is too small it does not annihilate the germs but merely modifies the paroxysms into atypical forms. Experience has authoritatively confirmed the value of the rule to give the quinin at the onset of the febrile paroxysm, graduating the dose to the type of infection: 2.5 gm. (40 grains) for the quotidian; 2 gm. (30 grains) for tertian, and 0.5 gm. (8 grains) for the quartan form. The paroxysm in question is apparently not affected by the drug but those that would follow it otherwise are suppressed.

44. **Improved Technic for Paraffin Treatment of Ozena.**—Leroux combines the advantages and avoids the perils of the hot and cold methods of injecting paraffin in treatment of ozena. This he accomplishes by injecting the paraffin cold, and several days later he applies a jet of superheated air to the spot under the influence of which the paraffin softens as if it had just been injected hot, penetrates into the crevices and spreads out in a more even layer. At the same time the hyperemia thus induced stimulates the secretions and aids in the cure of the ozena. He asserts that the injection of paraffin under the nasal mucosa is the only means of actual cure of this disease, all other measures having merely a palliative effect. He uses paraffin with a melting point at 45 C. and injects it in the inferior turbinate and the upper part of the septum, aiming to retain so far as possible the natural shape and size of the passages and facilitate the flow of air through them. It is important, he says, to commence at the remotest part and to allow time for the lesion to heal before making another injection.

48. **Operative Treatment of Stenosis of the Pylorus in Infants.**—Ochsenius reports 14 cases observed during the last three years and discusses the indications for operative treatment, which was applied in 2 cases with good results. The technic was simplified to a mere longitudinal incision about 2 cm. long in the enlarged and thickened pylorus. The incision was carried down through the pylorus musculature to the mucosa but the latter was left intact. The lips of the wound were then spread and sutured transversely to the axis of the pylorus. This, he states, accomplished the desired

result without making an opening into the stomach and the rapid recovery of the children confirmed the advantages of this technic. He regards the decline in weight as the index for the necessity of operative treatment, a loss of 34 per cent. in body weight being inevitably fatal; even 30 per cent. for breast-fed children and 27 per cent. for others is beyond the danger limit. The weight at birth gives an approximate base for estimation of the weight if records have not been kept. The children were all under 5 weeks old, and 2 died under medical measures only. The fate of the child lies in the hands of the internist; if a week or two of careful internal treatment shows no tendency to improvement an operation should be suggested, and this technic deprives it of most of its dangers. The after-treatment by the pediatrist and attendants is almost as important as the operation itself, Weber (who performed the operation) remarks. He is convinced that in many cases on record the operation would have been successful if the children had received proper attention afterward.

50. **Nature of Mountain Sickness in the Andes.**—Knoche describes the mountain sickness in the Andes as experienced by himself and his party, and emphasizes the importance of the electric charge in the atmosphere as the predominant factor in the sudden attacks of mountain sickness, describing the features and mechanism of the disturbance. The symptoms due to the rarefaction of the air should be distinguished from those resulting from the electric and radioactive elements. The latter are not observed in aviation. The violent, brief attack passes over in a short time, leaving no trace, and it occurs mostly in sheltered valleys.

62. **The Protean Manifestations of Visceral Syphilis.**—Kretschmer insists that the possibility of syphilis should always be borne in mind when confronted with any vague or atypical abdominal syndrome, especially when more than one of the viscera seem to be involved. In the first of the 6 cases of the kind reported, the participation in the syndrome of liver, spleen, intestines and kidneys and the absence of fever, jaundice and edema suggested a possible syphilitic origin, which was confirmed by a history of infection five years before and the gradual complete recovery under mercury and iodid. The only explanation possible is the assumption of multiple gummata in the abdominal organs and their entire retrogression. In two other cases the symptoms resembled those of a former patient explained at autopsy as congenital interstitial hepatitis; it was rebellious to all measures in both instances as also in a third case in which the diagnosis had been hypertrophic cirrhosis of the liver with compression of the bile ducts, but autopsy showed that they were patent. This patient was under observation for nearly 10 years; jaundice had recurred at intervals since childhood, but the patient bore a healthy child at the age of 23. In the fourth case a large tumor had developed in the abdomen three months after removal of an ovarian sarcoma. Some of the findings suggested pseudoleukemia, but a history of four abortions also suggested syphilis. Specific treatment for syphilis was combined with Roentgen-ray exposures and the tumor rapidly retrogressed while the general condition improved. The fifth patient presented a puzzling syndrome explained at autopsy as syphilitic iced liver and chronic adhesive peritonitis. The sixth case reported illustrates the evil of assuming a syphilitic affection when a harmless nervous or other disturbance is encountered in a patient with a history of syphilis in the past.

66. **Hyperemic Treatment of Habitual Abortion.**—Turan calls attention to two cases in which he was able to correct a tendency to habitual abortion by the systematic introduction into the uterus of a suction cannula. It not only induces hyperemia in the organ but stimulates it to muscular contractions, this exercise aiding in restoring normal conditions. In the first case he applied the cannula for half an hour at a time, at 20 sittings in the course of 7 weeks; in the second case the cannula was left for 10 hours at a time, the procedure being repeated 8 times in the course of one month. Both women have since borne healthy children, although there was a history of 5 and 3 abortions, respectively; the patients were 27 and 23 years old.

78 *International Institute for Medical Bibliography. (Grundzüge der *Organisation der medizinischen Literatur.*) E. Abderhalden.

68. **Prophylaxis of Epidemic Poliomyelitis.**—Römer and Joseph report experimental and clinical research which has confirmed the findings of Flexner, Lewis, Levaditi and Landsteiner. The extreme resistance of the virus is shown by persistence of full virulence for 28 days in a dried specimen in one of their tests on a monkey. Their research has further demonstrated, they state, that ordinary formaldehyd disinfection of apartments is sufficient to destroy the virus. The disease in monkeys confers immunity thereafter, suggesting the possibility of effectual clinical serovaccination. The domestic animals do not seem to convey the virus; transmission requires human contact, and healthy germ carriers are a formidable factor in the epidemic incidence of the disease.

71. Discussed editorially in The Journal, May 28, 1910, p. 1790.

72. **Transmission of Typhoid by Infants.**—Rommeler warns that when a nursing mother has typhoid and is sent to the hospital, the infant should accompany her as it is liable to have contracted the infection and, although apparently healthy, may yet serve as conveyor of typhoid bacilli. In the case reported, the infant was received into a friend's home when the mother was taken to the hospital. It was noticed that the child had a little diarrhea, but as it was being weaned, and seemed otherwise well, no attention was paid to this sign of trouble until one after the other six members of the family contracted typhoid and one died. The infant's serum responded positively to the agglutination test although the child kept comparatively well throughout.

75. **Rectal Gonorrhea in Children.**—Kaumheimer urges that greater attention should be paid to involvement of the rectum in case of gonorrhea, especially in children. This may be the cause of the unusual obstinacy of vulvovaginitis in little girls, the infection recurring again and again after the vulvar and vaginal lesions have been cured. The involvement of the rectum is seldom revealed by any clinical manifestations and thus it is liable to escape discovery. He warns in particular to refrain from taking the temperature in the rectum in patients with vulvovaginitis, unless extraordinary care to prevent conveyance of the infection is observed.

78. **Organization of Medical Literature.**—Abderhalden describes the principles on which is based this newly organized attempt in Germany to keep a comprehensive survey over the

entire field of medical literature in all countries. The aim is to publish a monthly index, something like the *Index Medicus*, absolutely complete, but in separate sections for each special field. This is to be supplemented by journals devoted to abstracts only, and each restricted to some special field. The system is completed by the year-books to compile and serve as a guide through the achievements of the past year, each in its restricted field. The centralblatts and year-books already in existence, three of which (biology, biochemistry and veterinary medicine) have already agreed to affiliate with the system, will enlarge their scope while restricting themselves more closely each to its special field. By intercommunication, distribution and exchange of material it is hoped thus to bring the medical literature of the world into a comprehensive and orderly arranged system whereby every article will be listed and important ones summarized and grouped for each reader in an accessible place. He adds that this has already been accomplished for stomatology and, in part, for chemistry.

Wiener klinische Wochenschrift, Vienna

May 5, XXIII, No. 18, pp. 651-684

79 *Characteristics of Cerebrospinal Fluid and Differential Diagnosis from its Examination. E. Mayerhofer.
80 Determination of Tubercle Bacilli in the Placentas of Tuberculous Mothers. J. Novak and F. Ranzel.
81 Decline During Measles of Specific Susceptibility to Vaccine. (Ueber Abnahme der spezifischen Vakzineempfindlichkeit während der Masern.) F. Hamburger and O. Schey.
82 Technic of Wassermann Reaction. (Verhalten von verschiedenen Extrakten bei der Wassermannschen Reaktion mit Berücksichtigung ihrer antikomplementären und hämolytischen Wirkung.) G. Satta and A. Donati.
83 *Influence of Heredity on Incidence of Gastric Ulcer. (Einfluss der Heredität auf die Bildung des Magengeschwürs.) W. Czernecki.
84 Treatment of Chancroids and Buboes. (Zur Behandlung des Ulcus molle und der Bubonen.) L. v. Zumbusch.

79. **Differential Diagnosis from Cerebrospinal Fluid.**—Mayerhofer states that the cerebrospinal fluid always reduces a permanganate solution when boiled with it, and that the intensity of the reducing reaction is an index of different pathologic conditions. He gives the details of eighteen cases to show the valuable information to be derived by this simple test. It can be applied also to the urine, and he is now studying it as applied to infants' urine. An exudate, of course, contains more organic substances than a transudate, and the differentiation is done by heating 1 c.c. of the cerebrospinal fluid mixed with 50 c.c. of distilled water and 10 c.c. of a 25 per cent. solution of sulphuric acid. Just as it boils, 10 c.c. of a one-tenth normal solution of potassium permanganate is added and the whole kept simmering for 10 minutes; when 10 c.c. of a one-tenth normal solution of oxalic acid is added and the fluid becomes at once limpid as this amount of oxalic acid decolorizes this amount of the permanganate solution. Then more of the latter is added until the first drop leaves a distinct and permanent rose-colored trail. Within 15 or 20 minutes of the lumbar puncture the test is complete. The number of cubic centimeters of the permanganate solution required is the index. In meningitis the index is from 2 to 8 while with normal fluid it is very small. After intradural injection of Vienna antimeningitis serum the index dropped to half its previous figure but no change was apparent after injection of serum of French origin.

83. **Heredity and Gastric Ulcer.**—Czernecki recently encountered a family in which the mother and four adult sons and daughters all presented gastric symptoms, and three had well-defined ulcers with a tendency to recurring hemorrhage. All the members of the family were typical examples of Stiller's universal asthenia and tendency to visceral ptosis. Such cases emphasize the importance of a tendency to ptosis in the etiology of gastric ulcer, and the necessity for general treatment in this direction, never restricting treatment of a gastric ulcer to the stomach alone.

87 *Intravenous General Ether Anesthesia. F. M. Pikin.
88 Intravenous General Hedonal Anesthesia. S. P. Fedoroff.

86. **Technic to Ensure Continence with Sacral Anus:**—Schmieden makes the new anus deep in the gluteal fold, with a small opening, and the peritoneum over the intestine is drawn together and sutured to form a comparatively narrow, long tube enclosing the intestine, and reaching as high up as possible. This is pushed back into the abdominal cavity. By this means the intestine opening at the artificial anus is enclosed in this long, narrow case for a considerable distance, and when stool approaches the anus its pressure in the peritoneal envelop early warns of its presence and thus muscular control can be brought into play. An illustration of the technic is given. In one case recent examination showed entire cure of the previous complete incontinence; there had been also a prolapse of the intestine in this case. The approach of fecal matter or gas gives warning and the patient is thus able with the help of the gluteal muscles to restrain it. Schmieden is convinced that this principle of high intraperitoneal reduction of the diameter of the gut represents progress in this line.

87. **Intravenous General Anesthesia.**—Pikin relates his experiences in fifteen cases with intravenous general anesthesia which were all favorable, but the sixteenth patient died in a few minutes after the commencement of the infusion of the ether solution. Burckhardt's technic was followed in every particular, but the method has been abandoned since this mishap. The communication issues from the surgical service at St. Petersburg in charge of Grekow.

Zentralblatt für Gynäkologie, Leipsic

94 Incision of Perineum. (Zur Episiotomie.) M. Stolz.

91. **Action of Roentgen Rays on the Ovaries.**—Reifferscheid reports extensive experimental research and six clinical cases in which the ovaries were removed after Roentgen exposures. In all degenerative changes were evident, providing a positive histologic basis for the numerous clinical successes in the therapeutic application of Roentgen rays. One patient was a woman of 37 with pulmonary phthisis on which account abortion was induced after seven Roentgen exposures. The ovaries were removed 18 days after the last exposure, 39 days after the first, and tubal sterilization was done at the same time. None of the follicles was normal in any of the ovaries; there were also signs of capillary hemorrhage.

Gazzetta degli Ospedali e delle Cliniche, Milan

April 26, XXXI, No. 50, pp. 529-536

95 *Constriction Hyperemia in Treatment of Alcoholic Tremor. (L'iperemia alla Bier e la sua applicazione in un caso di tremore alcoolico.) R. Migliaccio.

102 Successful Electrotherapy of Trigeminal Neuralgia: G. Viana.

95. **Constriction Hyperemia in Treatment of Alcoholic Tremor.**—Migliaccio reports prompt improvement of chronic alcoholic tremor in the hand after application of a constricting

band above for an hour and a half a day, with complete cure by the end of the month. The benefit in this case confirms, he says, that realized in writer's cramp, neuralgia and neuroses. Maragliano commends constriction hyperemia as the best method of treating contusions and sprains, and Migliaccio says that his experience has confirmed this.

98. **Operative Treatment of Hydrocele.**—D'Alberto commends Mannino's technic as simple, easy and reliable, while free from the drawbacks of other methods. It aims to obliterate the cavity formed by the vaginal tunic and promote the formation of adhesions. He separates the vaginal tunic from the scrotum part way around, working through an incision 5 cm. long. He then makes a similar incision in the vaginal tunic and after wiping it dry turns in the cut edges and sutures them to hold them back. The lips of the incision, thus reinforced, are then sutured. By this technic the outside of the testicle is covered with the outer side of the vaginal tunic thus folded back, while the two layers of the inner aspect are brought into contact and soon develop adhesions. The result was most satisfactory in the case reported; there has been no recurrence of the effusion, which had previously resisted tapping and other measures, including Volkmann's method of treatment. The patient was a man of 57.

112 Cammidge Reaction in Normal Urine. U. Sorrentino.

May 2, No. 18, pp. 477-504

113 Kala-Azar in Children and Adults. U. Gabbi.
114 Progressive Facial Hemiatrophy. R. Ciauri.

106. **Bilateral Hydronephrosis.**—The patient succumbed to uremic poisoning shortly after an operation to remove the obstructing stones from the right kidney. The left was also found hydronephrotic, with numerous stones. Zuccari declares that in hydronephrosis from calculi the kidney should not be removed for fear of involvement of the other kidney in a similar process, as renal lithiasis is bilateral in a large proportion of cases.

108. **Alimentary Levulosuria and Urobilinuria as Tests for Liver Functioning.**—Brun gave from 1.4 to 1.7 gm. of levulose and states that the resulting levulosuria was an easy, simple, delicate, practical, accurate and harmless method of determining the functional capacity of the liver. The slightest impairment was revealed by this means, as also the progress toward recovery or aggravation. He applied the test to 400 sick children and about 100 healthy ones, all from one month to 12 years old. The effect was practically the same whether the levulose was taken before, during or after a meal. The levulose appears in the urine by the second hour and persists through the twelfth. The normal liver does not permit the levulose to pass unmodified. He also concludes from his research that urobilinuria is not pathologic unless the urobilin occurs in very large amounts.

110. **Experimental Momburg Belt Constriction.**—Carere's experiments on dogs showed that no permanent disturbances resulted from the constriction by the Momburg technic. At the same time there was invariably a tendency to paralysis in the legs feeling the effects of the constriction, but it always retrogressed sooner or later according to the technic applied. When the tubing was over 1½ inches in diameter, serious injury to the abdominal organs was occasionally observed, but when Momburg's technic was strictly followed the disturbances were only transient.

FIELDS OF USEFULNESS OF THE AMERICAN MEDICAL ASSOCIATION*

WILLIAM H. WELCH, M.D., LL.D.

BALTIMORE

I wish to offer my hearty thanks for the signal honor of election to the presidency of this Association—an honor to which no member of our profession can be indifferent as a mark of the esteem and confidence of his colleagues and a high office of privilege and opportunity. The bestowal of this honor on one not engaged in the practice of medicine I interpret as a conspicuous recognition of the importance of those sciences on which this practice is founded.

In the recent death of Robert Koch the world mourns the loss of one of the greatest scientific investigators and benefactors of his race of all time—one who shares with Pasteur the immortal distinction of founding and developing the modern science of bacteriology, and establishing the germ theory of infectious diseases, which has had a revolutionary influence on practical and especially preventive medicine. To him we owe not only the introduction of the methods which have made possible the great discoveries in this field, but also the most fruitful exploration of the domain whose gates he had unlocked.

Since our last annual session there have passed away many eminent in our profession who have been identified with the work of this Association. Of those honored by the Association with high office, the especial tribute of our respect and grateful appreciation is due to the memories of Dr. Herbert L. Burrell, a recent president of the Association, distinguished surgeon and public-spirited citizen, to whom so much of the remarkable success of our sessions in Boston and Chicago was due, and of Dr. William Biddle Atkinson, the permanent secretary of this Association from 1864 to 1899—more than half the years of its existence—and for much of this time the editor of the *Transactions.*

To the honored roll of martyrs to medical science has been added recently the name of Dr. Howard Taylor Ricketts, who died in the City of Mexico from typhus fever, with which he was stricken while engaged in its investigation.

Aided partly by grants from the Committee on Scientific Research of this Association, Dr. Ricketts, by his important investigations, especially of Rocky Mountain fever and Mexican typhus, had acquired a place in the front rank of American pathologists. Scientific medicine in this country has suffered a serious loss by the untimely death of this brilliant young investigator.

MONUMENT TO YELLOW-FEVER COMMISSION

As it has always been the endeavor of this Association to secure suitable recognition of our medical heroes, we welcome with keen satisfaction the action of Senator Owen in introducing a bill in Congress, in line with a previous recommendation of President Roosevelt, appropriating the sum of fifty thousand dollars for a monument in Washington in honor of the Yellow-Fever Commission, composed of Major Walter Reed, Dr. James Carroll, Dr. Jesse W. Lazear and Dr. Aristides Agramonte, and commemorating also the men who submitted voluntarily to the experimental inoculations which resulted in the discovery of the mode of conveyance of yellow fever. The President of the American Medical Association, the Secretary of War, Major-General Wood, the Surgeon-General of the Army and Colonel William C. Gorgas are named as the commission to select the site and supervise the erection of this monument. This effort to perpetuate by worthy national recognition the memory of high courage and beneficent achievement will doubtless receive the endorsement and active interest and support of this Association.

MONUMENT TO MEDICAL OFFICERS OF WAR

In this connection, I may recall to your attention that, in accordance with the recommendation of my immediate predecessor, Dr. Gorgas, in favor of the suggestion of Dr. Weir Mitchell, the Association has already taken action looking to the erection in the national capital of a monument in memory of the medical officers on both sides who gave up their lives in the performance of their duties during the war between the states. This purpose to commemorate members of our guild whose services in a national crisis were for humanity should appeal strongly to the members of the profession throughout this country.

THEME: ACTIVITIES OF THE ASSOCIATION

It is my purpose in this address to call your attention chiefly to certain subjects suggested by some of the activities of this Association, with the desire of indicating to some extent and in a general way their nature and what has been accomplished, especially in recent years. Within the limits of an address none of these topics can be treated exhaustively, and many of equal importance must be left untouched. As the president has the opportunity of offering directly to the House of Delegates whatever specific suggestions he may desire to make, I shall not use this occasion for that purpose.

DEVELOPMENT OF SCIENTIFIC ASSOCIATIONS

The spirit of association is inherent in human nature. Although voluntary associations of those pursuing the same occupation and having common interests have existed from ancient times, it was not until the Renaissance that literary societies, nor until the rise of experimental science in the seventeenth century that scientific societies in the modern sense were formed. As is well known, these early societies, in which medicine was not separated from the natural and physical sciences, were powerful agencies in the advancement and diffusion of knowledge. The eighteenth century saw the development of separate local medical societies, both in Europe and in this country. Before the end of this century not less than seven of our state medical societies had been created, the first being that of New Jersey. The original charter of the Connecticut Medical Society, incorporated in 1792, is historically almost as interesting as the famous Connecticut constitution of 1639, for it embodied the essential federative feature of the present plan of organization of our state and national associations by constituting the county society as the unit with representation by delegates in the state society.

---

* President's Address at the Sixty-first Annual Session of the American Medical Association at St. Louis, June 7, 1910.

A new type of scientific society, of national scope and characterized by periodical, migratory meetings, originated in 1822, chiefly through the efforts of von Humboldt, by the formation of the still flourishing *Gesellschaft Deutscher Naturforscher und Aerzte.* The occasion for the formation of this and later of many similar societies is to be sought mainly in the growth and organization of science, with the consequent greater need of intercourse, as well as in improved facilities of travel.

ORIGIN OF AMERICAN MEDICAL ASSOCIATION

It is to this type of itinerant national society with annual meetings that the American Medical Association, started in 1846, belongs, and, although sixty-four years is a brief life in the history of institutions, still our Association not only is the first example of this pattern of society in this country, but it is one of the oldest of the kind in the world, being preceded by the German society mentioned, the British Association for the Advancement of Science in 1831 and the British Medical Association in 1832.

Although the origin of the American Medical Association is to be traced to a national convention of delegates from medical societies and colleges, called by the Medical Society of the State of New York, mainly through the efforts of Nathan Smith Davis, to elevate the standard of medical education, then in a most deplorable condition in this country, it may be recalled that the same society as early as 1839 adopted a resolution offered by Dr. John McCall with the following preamble: "A national medical convention would advance, in the apprehension of this society, the cause of the medical profession throughout our land, in thus affording an interchange of views and sentiments on the most interesting of all subjects—that involving men's health and the means of securing or recovering the same." Although the steps then taken to secure this end proved fruitless, it was more in accordance with the broad spirit of Dr. McCall's resolution than with the narrower, though important purpose determining the call of the convention of 1846 in New York that the organization of the American Medical Association was effected at the meeting in Philadelphia in 1847, when the purposes were declared in the preamble to the constitution to be "for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those engaged in it."

Our present constitution, adopted in 1901, has not added to or changed materially these excellent purposes as originally declared, save in one particular, which is significant of the progress of medicine and the relations of physicians to the community. "The broad problems of hygiene" are substituted for "the duties, responsibilities and requirements of medical men" as the subject for enlightenment and direction of public opinion.

EARLY ORGANIZATION

At the birth of the Association much discussion was given to the question whether it should be organized as a representative body or as a self-constituted and self-perpetuating society, electing its own members. It is curious to think what would have been the history of the Association had not the wiser choice been made, in favor of the more democratic, representative plan. This plan, which continued in operation for fifty-five years, provided for representation not only from permanently organized medical societies, whether local, district or state, but also from medical colleges, hospitals and other institutions, every ten members of an auxiliary society being entitled to a delegate and only the delegates having a voice in the conduct and affairs of the Association. However cumbersome and ineffective this basis of representation became with the growth of the profession and of the country, it was well suited to the conditions existing at the time of its adoption.

FIRST HALF-CENTURY

The Association has grown so rapidly and achieved so much since its improved organization nine years ago, that we are in danger of losing sight of the great service which it rendered to the profession during the preceding half-century, in spite of defects and failures and errors. The founders of the American Medical Association brought into being a national organization, truly representative of the whole medical profession of this country. Such an organization has inherent elements of strength which secure its future even against its own blunders and still more against attacks from without. In spite of an unfortunate incident in its history the Association has been from the beginning the great unifying force for the profession of this country, whose common interests it has been its chief endeavor to serve. Since its foundation it has had the devoted loyalty and faithful services of many leaders of the profession.

English and American physicians of the early part of the last century were greatly inspired by the work of the admirable Manchester physician, Dr. Thomas Percival, entitled "Medical Ethics," which appeared in 1803, and many medical societies of that period adopted codes of ethics based upon the precepts of this excellent book. The American Medical Association followed this custom in framing such a code and thereby exerted a distinctive and beneficent influence upon standards of professional conduct throughout this country. Although in form and certain details this code became obsolete, its underlying principles are enduring.

The central object of the organization, the cultivation of medical science and art, was always kept clearly in view. The condition and the progress of American medicine are well reflected in the thirty-three volumes of our *Transactions,* followed by THE JOURNAL, established in 1883. My memory goes back to attendance on meetings in the late seventies and I recall attractive programs, inspiring addresses, valuable scientific papers, agreeable personal and social intercourse and generous hospitality.

What the Association was able to accomplish in the first fifty-five years of its existence in regard to such matters of professional and public interest as medical education, legislation, organization, protection from fraud, is insignificant in comparison with the achievements of the last decade, but this failure was not due to lack of effort or of interest or of realization of the conditions. The fault was mainly in the machinery of organization, long recognized as outworn and inadequate, which rendered practically impossible orderly and effective transaction of business, deliberate and well-considered action, and the adoption and carrying out of any continuous policy or undertaking.

NEW ERA

My object in this brief reference to the past of the Association is not to trace details of history, but to indicate, in the first place, that improvement in organization was urgently needed and, secondly, that the improved organization effected nine years ago marked no break with the past, but was in the nature of an orderly evolution along predetermined lines toward larger and better things. The past decade is often spoken of as a new era in the life of the Association, and such it is, although only in the sense that it is characterized by the attainment of results long desired and long striven for and by possibilities of ever-increasing usefulness.

IMPROVED ORGANIZATION

The much-needed but very simple change in the form of organization effected in 1901 after full discussion and mature consideration was in its essential features identical with that proposed in 1887 by a committee of which the founder of the Association, Dr. Nathan Smith Davis, was chairman; and there can scarcely be found a more striking illustration of the defects of the old plan than the long delay in the adoption of this proposal, a delay resulting not from opposition, but from sheer inability to secure proper deliberation and effective action in the business meetings. It is gratifying and worthy of note that both the earlier and the present plans of organization should embody so largely the conceptions of one man, whose great services to the profession and the public as founder of this Association and for more than half a century zealous promoter of its welfare, as eminent physician and educator, and as public-spirited and far-sighted citizen should stir the members of the Association to more active efforts in behalf of the Davis memorial fund, so that the sum of $5000 conditionally appropriated to this purpose by the trustees may be rendered available.

By basing membership and the right of representation in the Association on the state associations, by creating a delegated business body, large enough to be truly representative but not so numerous as to be ineffective in the transaction of business, and meeting separately from the general and scientific sessions, and by securing on the part of the state associations the adoption of the county society as the unit of the system, a federative organization of the medical profession of this country has been brought about as simple as it is effective. Whatever may be needed in perfecting details of this plan of organization, the experience of nearly a decade has demonstrated convincingly the soundness and wisdom of its fundamental features.

Organization, however carefully devised by man, is inert until it acquires living force by the efforts of those who set it in motion, and the good accomplished depends far more on the character of these efforts than on the instrument employed.

The Association in these latter years has been fortunate in enlisting the adhesion and cooperation of many of the best workers in the profession and even in allied fields, who have given unselfishly their time and energy and thought to work in behalf of professional and public interests; but there are two men, entrusted with most important official duties, whose services have been so conspicuous and are so deserving of the gratitude of the profession that it is only just to mention their names in this connection: Dr. George H. Simmons, who, as General Secretary and manager and editor of THE JOURNAL, has done more than any one else to determine and further the policies of the Association and to place it in its present high position of influence and usefulness; and Dr. Joseph N. McCormack, who, in connection with his valuable work as organizer, has preached the gospel of public health throughout the length and breadth of this land.

ACHIEVEMENTS OF LAST DECADE

Among the more striking beneficial results accomplished by the Association during the past decade I may enumerate the unification and effective organization of the profession; the growth of the national and constituent associations in membership and influence; the development of THE JOURNAL to an importance unsurpassed by any medical weekly in the world; the improvement of the educational and scientific work of the Association through its sections, its scientific exhibit, its grants in aid of research, and the public lectures and addresses of Dr. McCormack; the establishment of the Council on Pharmacy and Chemistry with its chemical laboratory, the Council on Medical Education, the Committee on Medical Legislation, the Council on Defense of Medical Research, the Committee on Ophthalmia Neonatorum, the Committee on Nomenclature and Classification of Diseases, the Board of Public Instruction on Medical Subjects, the Women's Committee on Public Health Education (the status of which, however, awaits clearer definition) and other special committees supported by funds of the Association and working continuously; the compilation and publication of two editions of an authoritative medical directory, owned by the profession; the foundation and publication, without expense to the Association, of the *Archives of Internal Medicine,* in order to meet an urgent need of higher clinical medicine; and, finally, the erection of a new building to accommodate the printing plant and working forces of the Association. This is indeed a record of large and beneficent achievement To describe in any detail the results of the activities here enumerated would far exceed the limits of this address; but on a few of the more significant ones permit me to touch.

COUNCIL ON PHARMACY AND CHEMISTRY

Of the work accomplished by councils and committees that of the Council on Pharmacy and Chemistry is the most notable, and merits the high commendation which it has received from the profession and the enlightened public. A check has at last been put on the exploitation of the profession and to a considerable extent likewise of the public by the strongly entrenched and widely ramifying patent-medicine evil with its shameless frauds, misrepresentations, deceits and dangerous practices. The work of this Council has assumed international proportions and it is gratifying to note that legitimate pharmacy and the respectable manufacturing pharmacists are coming to appreciate more and more its benefits to them.

MEDICAL EDUCATION

For the last six years the Council on Medical Education, by steady, continuous, well-directed work, including personal inspection, has been engaged in collecting and publishing a vast amount of accurate, detailed information concerning the medical schools and every phase of medical education in this country. Its conferences have been attended by leading educators, and the addresses and discussions on these occasions have been interesting and valuable. The purpose of all this work has been constructive and not critical. The facts elicited, as well as those published in the highly important "Report on Medical Education of the Carnegie Foundation for the Advancement of Teaching," which has just appeared, while confirmatory of general impressions, acquire impressive significance when marshaled in concrete, statistical form and are of enormous consequence to the medical profession and the community. The attitude of physicians should be clear in this matter, for the strength and credit of the profession, the great interests of public health, municipal, state and national, and the welfare of the individual all depend on the quality of training given in our medical schools.

The immediately urgent directions of improvement are reduction in the number of poorly supported, existing medical schools by demise or by merger, provision of adequate financial support beyond the fees of students, the elevation and, even more, the conscientious enforcement of the requirements for preliminary training and of standards, the maintenance of at least five well-equipped laboratories conducted by teachers giving their whole time to the work, far better clinical training, such as can be given only in a hospital owned by the school or affiliated with it as its teaching hospital, and realization on the part of universities of their responsibilities for their departments of medicine.

The argument that the country needs to-day, if it ever did, cheap and inferior medical colleges is wholly fallacious, for we have at present in this country practically as many medical schools as all the rest of the world combined, and four to five times as many doctors in ratio to the population as Germany and the older civilized countries; and, moreover, graduates of low-grade schools manifest no peculiar inclination or tendency to seek remote and unpromising localities, but prefer competition in fields already overcrowded.

There have been in recent years influences in operation tending to a diminution in the number of medical schools and of students of medicine. Among these influences may be recognized the inevitable pressure exerted by the demands of state licensing boards and an awakened sense of loyalty and duty to the profession on the part of some of the weaker schools and of many physicians in consequence of fuller realization of the educational requirements of modern medicine, but, as the phenomenon is world-wide, some deeper causes are operative. There may be larger recourse to certain special healing cults and a growing discrimination on the part of the public between well-trained and ill-trained physicians; but more significant is the lessened demand for the services of physicians, resulting from the marked diminution in the amount of disease, especially the acute infections and tuberculosis, as the result of modern sanitation and public health movements, and the increasing tendency of rich and of poor alike to seek treatment for medical as well as surgical ailments in hospitals.

Certain of these conditions afford much food for serious thought, as they are of great economic importance to the medical profession, but I cannot pause to discuss them on this occasion, save to remark that new and rewarding opportunities and a new mission of service are opening to properly trained physicians in the great fields of public hygiene and preventive medicine. It is a serious defect of our medical schools in general that they do not at present provide adequate training for work of this character.

The outlook for improvement of medical education in this country is most encouraging. We already have a few excellent medical schools, comparable with the best in Europe, and the general average is rapidly advancing, so that we need not despair of attaining conditions of medical education which shall cease to be a reproach to us. The reform of medical education in this country is moving forward by the aid of many agencies and influences, and when its history is written the work of the Council on Medical Education of this Association will fill an important chapter.

The City of St. Louis to-day offers in the reorganization of the medical department of Washington University the finest possible example of improvement in medical education and the way to accomplish it. This medical school, aided by splendid gifts of enlightened benefactors and by the affiliation of a group of admirable hospitals and broadly planned with clear recognition of the needs of modern medicine, is destined to be among the foremost in this country and to exert a strong influence on medical education throughout the land, and especially in the middle West and South. I am sure that my colleagues of the American Medical Association desire me to extend, on this occasion and in this place in their behalf, our hearty congratulations and best wishes to Washington University and its medical school and to express to the donors our grateful appreciation of their generous benefactions to the cause of higher medical education and thereby to humanity.

ANIMAL EXPERIMENTATION

The Council on Defense of Medical Research is performing well a duty which we owe not only to the present generation, but to all who are to follow us, for there would be little hope for the future of medical education or the progress of medical science and art if medicine were deprived of the method of experimentation. This method, which from the nature of the subject matter must consist largely in experimentation on animals in the biologic and medical sciences, is for the science of medicine precisely what it is for chemistry and physics, its greatest lever of advancement. Observation and experiment are the warp and woof of the fabric of scientific medicine, the one as necessary as the other. Animal experimentation, however, differs from experimentation with inanimate matter in that it should never be undertaken without a serious purpose and a grave sense of responsibility to avoid the infliction of all unnecessary pain; and it is a fact that in no other use of animals for the benefit of man is equal solicitude exercised in this regard.

The antivivisectionists are engaged in an utterly hopeless undertaking in their attempts to convince the public that experimentation on animals is of little or no benefit to mankind. As all physicians know, these benefits are simply inestimable, and one is almost inclined to welcome an agitation which has afforded us the opportunity to present to the public conclusive evidence on this question in the admirable papers already published and in course of preparation under the supervision of the Council on Defense of Medical Research, which is doing a work comparable to that of the British Council on the same subject. These papers, issued in pamphlet form, have been widely circulated and are at the service of any one who desires to use them.

In their charges of wanton cruelty brought against physiologists and physicians, as well as in their efforts to demonstrate the inutility of animal experimentation, the antivivisectionists have long conducted an agitation unmatched for recklessness of statement, slanderous misrepresentation and deceit, unbounded credulity, and ignorance, through any personal knowledge, of the object of their attack or of its relations to the interests of science and humanity. The agitation for the prohibition of experiments on animals, conducted under the guise of an humane purpose, is fundamentally inhuman, for if it were to succeed the best hopes of humanity for further escape from physical suffering and disease would be destroyed.

Those who are familiar with the conditions of animal experimentation as practiced in this country and are most competent to judge are convinced that no further legislation relating to the subject is needed. No special legislation regulative of this practice and at all acceptable to those who seek such regulation has ever been proposed which is not open to serious objections as interfering with useful and proper experimentation and subjecting experimenters to unnecessary and intolerable restrictions, supervision and annoyance. The enactment of such legislation in Great Britain has been a stimulus rather than a quietus to continuance of the pernicious agitation and has been detrimental to the interests of medical science and art in that country. Vigilance in guarding against the enactment of legislation of this character in any part of this country is a duty which physicians owe to the science and art which they cultivate and to the welfare of the community.

MEDICAL AND HEALTH LEGISLATION

This Association as the representative of the medical profession of this nation cannot and should not be indifferent to legislation relating to important matters of public health and medicine, but the determination of the precise character and extent of its activities in this field is a question of considerable difficulty which we have not as yet fully and satisfactorily solved. The Association should assuredly keep aloof from politics in the customary significance of this term, and it should never resort to the arts of the politician. It should never appear in advocacy of legislative measures which are not clearly for the public welfare. Being a national organization, it should not intervene actively in state legislation, although here it may be helpful in an educational and advisory capacity. Its function and indeed its duty in relation to national legislation concerning health and medicine is to utter the voice of medical science as effectively as possible and to endeavor to have it heard by the lawmakers. It was entirely right and proper for this Association through its Committee on Medical Legislation to aid in the defeat of the antivivisection bill before Congress ten years ago and to support the passage of the Food and Drugs Act, the pensions for the widows of our medical heroes, Reed, Lazear and Carroll, the introduction of trained nursing in the army, the various public health bills, including the one now under consideration for a department of public health, and indeed, I believe, of every bill which this committee with varying success has advocated in Congress.

When Congress manifests such ignorance and indifference to urgent demands of sanitation as it did in framing the bill constituting the Isthmian Canal Commission, which took the fullest cognizance of the engineering problem and utterly ignored the equally important and not less difficult sanitary problem, the Association would have been culpable in not directing attention to the omission and in failing to urge the appointment as a member of the Commission of the eminent sanitarian whom I am proud to succeed in this presidential office, and who had already given proof that if any one could conquer the pestilences which had frustrated previous attempts to construct the canal, he was the man. And how well he has justified our faith by achieving the greatest triumph in practical sanitation in history!

The field of usefulness for this Association regarding legislation properly within its purview, includes, however, more than the advocacy or disapproval of specific laws already framed; it embraces likewise such matters as the collection of facts, legal opinions, historical data and information bearing on the questions concerned, the careful study of fundamental legal principles and of existing conditions in order to know what is right and also what is practicable, the examination of medical and sanitary laws, administration and activities in this country and abroad with a view to useful recommendations, the discriminating consideration of the powers and functions of the national government and of state and local governments respectively in the protection and promotion of the public health, cooperation with other agencies and efforts, especially those endeavoring to secure greater uniformity in state legislation by framing model laws relating to vital statistics, medical licensure, pure food and drugs, and the like, and the education of public opinion in support of laws for the common good, which are the only laws in which this Association has any interest whatever.

Since the establishment of the Bureau of Medical Legislation at the Association headquarters three years ago a good beginning has been made in constructive work of this character. The interesting and exhaustive discussion on a model law for the regulation of the practice of medicine at the joint conference of the Committee on Medical Legislation and the Council on Medical Education held in Chicago last March, while it constituted a most valuable contribution to this intricate and perplexing subject, brought out the lack of agreement on fundamental principles and forcibly exemplified the need of such preliminary work as I have indicated.

VITAL STATISTICS

The framing of a model bill for the registration of vital statistics, combined with the excellent work of the Committee on Nomenclature and Classification of Diseases, should greatly facilitate the extension of the area of registration of births and deaths in this country and improve conditions within the registration area. Vital statistics is the very foundation of sanitary science and of practical sanitation, and its neglect in this country has been as much of a reproach to us as our low standards of medical education. The Association and all the physicians of the country should do their best to remove this reproach as rapidly as possible. The intimate connection of accurate registration of births with public health problems may be illustrated by the emphasis justly placed upon it in the admirable reports of the Committee on Ophthalmia Neonatorum. This Committee, whose work is a great credit to the Association and has become an important factor in the stirring campaign for the prevention of blindness, is brought likewise into close contact with another serious legislative problem, namely, the regulation of midwifery practice.

DEPARTMENT OF HEALTH

Most gratifying is the awakening of sentiment beyond the confines of the medical profession in favor of the creation of a department of public health in the national government, of which this Association in its official action has long been an earnest advocate. It is especially significant that economists, experts in life-insurance, those interested in the industrial and social conditions of the laboring classes and others whose occupations and studies lead them to a realization of the enormous waste of life and energy from preventable diseases have espoused the movement for greater activities of the federal government in the protection of the people's health. The Committee of One Hundred, originating as a committee of the section of social science and economics of the Association for the Advancement of Science, which represents science in this country as our Association represents medicine, has done an important and patriotic service in educating public opinion and stirring up interest in this great cause.

I do not see how any intelligent and patriotic citizen who has studied the question can fail to reach the conclusion that the federal government should do far more than it is doing in the promotion of public health, and that such increased activity, properly directed, would be of incalculable benefit in the saving of human life, health and energy. I agree with the great majority of the members of this Association that the best way to secure this result is by the creation of a national department of public health. While it may be that a mature and detailed plan of organization for such a department has not yet been devised, the primary and essential thing is to demonstrate the need, and this, I believe, has been done. The Public Health and Marine-Hospital Service is already a partial bureau of health with an excellent hygienic laboratory, so far it has been developed. Its incorporation in a department of health would enable it to increase its functions and expand its usefulness. There are many suggestive analogies between the growth, functions and general plan of organization of the Department of Agriculture and the corresponding features of the proposed department of health and the argument for the establishment of the latter is stronger than was that for an agricultural department when this was formed.

Those who have been fighting for years the battles of public health in this country and have been discouraged by the indifference of our national legislators to this subject in its relations to the federal government have been inspired in the last few months by the appearance in the Senate of the United States of a champion of this cause, Senator Owen of Oklahoma, who, with an intelligent grasp of the significance of preventive medicine for the conservation of the human resources of the nation, has vigorously urged the need of further action by Congress in this direction, and has introduced a bill for the creation of a federal department of public health. The principles of this bill—and it is only on the principles, not the details, that Senator Owen himself lays importance—have been endorsed by the Committee on Legislation of this Association, the Committee of One Hundred, and a large number of eminent physicians, sanitarians and others who have interested themselves in the matter.

SECTARIAN MEDICINE

The introduction of Senator Owen's bill has been made the pretext for an attack on this Association of such a preposterous nature and led by interests of such a character that there is no occasion for our concerning ourselves seriously with it. We represent no school of medicine and no system of healing, allopathic, old, regular or other. We are simply physicians, as chemists are chemists and physicists are physicists, seeking to advance the boundaries of medical knowledge and to base, so far as possible, the practice of our art on scientific principles and sound experience. Our concern with the legal regulation of the practice of medicine differs in no respect from that of the rest of the community and is merely that those who assume to practice the healing art as a profession shall have some adequate knowledge of the human body in health and in disease. While we know, as all men of science must know, that there can be no dogma, principle, system or method universally applicable to the treatment of disease, we are aware that new knowledge may come from the most unpromising sources, and we are eager to discover what good there may be in the claims of the advocates of any peculiar system of treatment; and if such is found, there is nothing whatever in our principles to prevent us from adopting it, or, in fact, from employing any method of cure which the physician may deem best. We have no intention or desire to interfere, even if we could, with the freedom of the individual to employ any one or any method of healing he may please, so long as the interests of public health are not endangered thereby. Incredible as it may seem to those whose vision does not extend beyond personal and commercial interests, we are engaged in the campaign for public health from purely altruistic motives, for we hope the day is not far distant when there will be less disease to demand the services of physicians.

The idea that a federal department of health could have anything whatever to do with the regulation of the practice of medicine throughout the country merely betrays abysmal ignorance of the constitutional principles of our government. Of the two great divisions of medicine, it is only with the curative that sectarian medicine has concerned itself, while to the preventive side, where our great conquests lie, it has contributed nothing. It is not surprising that the better representatives of sectarian medicine, realizing the false position in which it has been attempted to place them, should have hastened to disclaim any connection with the grotesque movement organized to defeat the creation of a federal department of health on the ground that it is favored by the great body of physicians of this country represented in this Association.

INTERNATIONAL CONGRESS OF HYGIENE

Had time permitted I should have been glad to speak of other activities of the Association, particularly the somewhat scattered ones in the field of public hygiene. Here I shall only remind you that the important International Congress of Hygiene and Demography, which is to meet in this country in 1912 on invitation of the government, will doubtless be of great interest and should give a powerful impetus to the movement for better sanitary administration throughout the country.

GEORGE WASHINGTON MEMORIAL ASSOCIATION

The difficulty of housing such a congress in the national capital and our experience in this respect in caring for the International Congress on Tuberculosis in 1908 bring home to us forcibly the importance of aiding the efforts of the George Washington Memorial Association, already endorsed by this Association, to provide in the City of Washington a suitable building containing halls, lecture rooms and a large auditorium for the accommodation of national and international congresses.

NEED OF ECONOMY

My service for six years as a Trustee of this Association leads me to remind the members that our funds are relatively small in comparison with the fields of usefulness which we would like to cover. This condition necessitates careful consideration by the Delegates and the Trustees of the numerous proposals in order to select those which seem to belong most properly to the sphere of the Association and are not adequately provided for by other agencies, and of these to choose the ones which appear to be most important and most urgent and to give promise of the most rewarding results. Experience has shown that the best returns are obtained from systematic, centralized work continuing over a number of years.

SECTIONS AND SCIENTIFIC EXHIBIT

While I have devoted the larger part of this address to the consideration of certain subjects of wide professional and public interest which have properly engaged the attention of the Association in its capacity of national representative of the great body of physicians of this country, it should never be forgotten that the main purpose of this organization is that which is placed first in our constitution—the promotion of the science and art of medicine. All of the activities should center around this purpose and be contributory to it. These central educational and scientific functions are most effectively served by The Journal and by the meetings of the various Sections at the annual sessions. It is these more than aught else which interest the members of the Association and which hold the organization together. Their development and success should always be the first thought and highest endeavor of the Association.

The scientific exhibit, under the energetic, self-sacrificing direction of Dr. Wynn, to whom the Association owes a large debt of gratitude, has grown into one of the most useful, attractive and instructive features of our meetings, with promise of even wider and more varied scientific and educational value. It has already gained a position which, to say the least, is coordinate in interest and importance to a section, and it should receive every possible encouragement and support from the Association.

ORGANIZED EFFORT

Organized effort is a distinguishing mark of modern civilization. It is as essential for the advancement of science, of education, of social and industrial reform, of philanthropic endeavor, as for the promotion of commerce. With the remarkable progress of medical science, especially during the last three decades, man's power to control disease has been vastly increased, and the sphere of usefulness of the physician has been correspondingly widened, and with advancing knowledge will continue to expand. The skill and knowledge of the physician and sanitarian have acquired a new and ever-increasing importance and significance in the movements for social amelioration, for improvement of the conditions of labor and of living, for the conservation and most efficient utilization of the productive energy of the world, and for the reclamation of regions now yielding no return to civilization.

Among the organized forces for advancing the prosperity, the happiness and the well being of the people of this country, the American Medical Association has an important part to play. We are justified in the confidence that, with the united support and loyalty of the profession, this Association, broadly representative and standing for the best ideals of medical science and art and for professional and civic righteousness, will contribute a beneficent share to the working out of our national destiny.

807 St. Paul Street.

THE IMPORTANCE OF THE EUGENIC MOVEMENT AND ITS RELATION TO SOCIAL HYGIENE*

LEWELLYS F. BARKER, M.D.
Professor of Medicine in Johns Hopkins University and Physician-in-Chief to Johns Hopkins Hospital
BALTIMORE

> "Like leaves on trees the race of man is found,
> Now green in youth, now withering on the ground;
> Another race the following spring supplies
> They fall successive and successive rise."

If it be true that the whole human race gets a fresh start at least thrice every hundred years; that the kind of race in existence in any period depends on the quality of the children born and the influences to which they are exposed after birth; that the supreme reason for marriage is parenthood; that the quality of children born depends (1) on the elements inherent in the germ-cells of the parents, and (2) on the environment of those germ-cells before their union and also after their fusion to form a new being; that a critical study of the relatives of a prospective parent will give valuable evidence regarding the nature of the elements—good, bad and indifferent—inherent in his or her germ-cells and likely to be transmitted; that poisons like alcohol, lead, or the toxins of syphilis circulating in the blood of either parent before a germ-cell union, or and more especially, in the blood of a mother before the birth of her child, may make the offspring the victim of malformation, infantilism, mental defect or epilepsy—if these things be true I think it probable that it would be possible and wise to interest young and marriageable people in the facts, and to a certain extent consciously to direct selection by marriage, and further, consciously to protect from injury germ-cells which possibly may fuse, or have already united to form a new human being.

CREATE PUBLIC OPINION

If it be true that the quality of human beings born depends on the inherent qualities of the germ-cells of the parents and their environment before and after fusion, may it not be possible by education to cultivate a public opinion that will lead families to show as much pride in making provision for characteristics of health, energy, ability, courage and courtesy in their posterity as some of them now evince in their ancestry? May not family sentiment be developed in the direction of suppressing parenthood in the racially unworthy and of facilitating fatherhood and motherhood for those who are able to transmit to their offspring desirable qualities unhampered by glaring defect? In the words of Zarathustra, may we not say to the family: "In the future let not your pride be whence ye have come, but whither ye go."

---

* Read before the Maryland Society of Social Hygiene, April 19, 1910.

If it be true that those born deaf and dumb, or feeble-minded, or with an insane or epileptic tendency, or color-blind, are likely to propagate their kind; and if it be true that the chronic inebriate, the prostitute, the drug habitué and the habitual criminal are, as a rule such because of the nervous systems they have inherited, and that they are likely to transmit defective nervous systems to their offspring, it would be desirable to educate public opinion, not only to discountenancing, but actually to legislative prohibition of parenthood for individuals so afflicted.

THE FIT AND THE UNFIT

If it be true that the decline and fall of nations following from no apparent external causes is really explicable through "the relative fertility of the fitter and unfitter elements combined with what we now know of the laws of inheritance;" if it be a fact that the success of a people usually leads to a cessation of natural selection within that people, and hence is often followed by survival of the worse; if we can be convinced that by applying scientific knowledge it would be possible to stem racial decadence and determine a racial ascent, surely there could be no more laudable, patriotic movement than one which will help a nation in its struggle by seeing to it that the children of that nation have their origin in the fusion of the better germ-cells available, and that those germ-cells and those children are protected from the injury which results from undernourishment or from the action of such racial poisons as alcohol, lead, and the toxins produced by infectious agents. We do not have to look far afield to observe that certain of the civilizations in existence today are trying to apply every scrap of biologic knowledge which they believe will help them in the struggle; woe be to the societies and nations which fail to apply this new knowledge as it accumulates; the fate of such negligent or non-compliant communities is sealed; they are making no proper effort to postpone the time when they will be "one with Nineveh and Tyre."

If it be true that as the human race advances and the range of intellect widens, the tendency is to work for the future of humanity as well as for its present good; if, from the time of Plato to our day, the best minds have cherished the idea of a more perfect state, and have urged the suppression of human baseness and the creation and the appreciation of a "super-man;" if modern science has placed in our hands the key which unlocks the box containing the secret of race-ennoblement, namely, the picking out by preference of the racially superior for parenthood combined with the protection of childhood and the support of maternal care by fatherhood—if these be facts, then the phenomena of sex may ultimately come to be regarded by more people with awe; parenthood will be looked on as the noblest and most sacred of functions, entailing the heaviest responsibilities, and "the science which deals with all the influences that improve the inborn qualities of a race" (Mr. Francis Galton's definition of eugenics), will become a constituent of the higher human religions.

EUGENICS

The science which has for its object the prevention of the birth of the unfit and undesirable, and the improvement of the race by furthering the productivity of the fit and the desirable by early marriages and by healthful rearing of children, has been called by Mr. Francis Galton, whose life has been devoted to a campaign in favor of it, the science of eugenics. Whereas, natural selection depends on overproduction and wholesale destruction, the aim of eugenics is to see that no more children are born than can be properly cared for and to make sure that those born come of the best stock. This science assumes that it is possible to improve the race by the application of the newer knowledge which modern studies of heredity and environment have yielded.

Until recently young people approaching marriage have had no way of obtaining definite information concerning fit and unfit matings and many of them have never been taught to consider whether or not a proposed marriage would lead to the birth of children with healthy bodies and sound and able minds. Students of heredity and of hygiene are now making the effort to supply the much-needed information and we must be grateful for the various publications which have recently attempted to present in a popular way the existing state of our knowledge concerning these vital matters. For those who wish to begin a course of reading along eugenic lines I would recommend:

C. W. Saleeby: "Parenthood and Race Culture: An Outline of Eugenics" (New York, 1909).

W. Bateson: "Methods and Scope of Genetics" (Cambridge, 1908) and his "Mendel's Principles of Heredity" (Cambridge, 1909).

T. H. Morgan's "Experimental Zoology" (New York, 1907).

C. B. Davenport: "Eugenics: The Science of Human Improvement by Better Breeding" (New York, 1910).

Karl Pearson: "National Life from the Standpoint of Science" (Edinburgh, 1905).

R. R. Rentoul: "Race Culture or Race Suicide" (Edinburgh, 1906).

In the first book mentioned references will be found to the more technical sources, including J. A. Thompson's Heredity, Francis Galton's publications, Westermarck's "History of Human Marriage" and Forel's "The Sexual Question."

PUBLIC INTEREST IN EUGENICS

There is now in existence in England a Eugenics Education Society, and the publication of a *Eugenics Review* has been begun. In this country the American Breeders' Association has organized a Committee on Eugenics for purposes of investigation, education and legislation. In Germany there is an excellent journal called the *Archiv für Rassen-und Gesellschafts-Biologie.* It seems probable that eugenic societies, eugenic committees and eugenic publications will rapidly multiply, and it is not at all improbable that wise philanthropists, seeing that the millions of dollars now used for caring for the weak and defective help only one generation, will soon be induced to provide large sums for eugenics, with the idea of preventing the production of the imbecile, the insane, the inebriate and the criminal.

MENDELIAN LAWS

My purpose now is not to dwell at any length on studies in heredity or the various theories which have been devised to interpret its phenomena. There have been, however, certain developments in the study of heredity to which as yet popular attention has been insufficiently drawn; I mean the rules regarding inheritance which have resulted from the experimental studies begun by the Abbot Gregor Mendel in the cloister garden at Brünn about a half century ago. For a time it seemed possible that these studies held good more particularly for the life of plants and of lower animals, but of late there has been a rapid accumulation of evidence which makes it seem certain that the Mendelian rules are also valid, at any rate to a large extent, for the higher animals and man. It now seems probable that inquiries into the physiology of heredity and variation will progress largely by the application of experimental methods similar to those which grew out of Mendel's discovery.

For a long time it has been known that most animals and plants begin life by the union of two cells, the one male, the other female. Biologists describing those cells call them gametes; that is, germ-cells or marrying-cells. These germ-cells contain in some way or another the factors on which all the powers, both physical and mental, possessed by the living creature to which they give rise, depend. It was Mendel who first appreciated the full consequences of the double nature of each individual being, due to the fact that two cells are concerned in its production. To understand the facts of heredity it will no longer do to think of a boy or a bee or a beech-tree as each being one thing, but we must think of each of them as being two things, indeed, as being double in composition throughout.

It is no uncommon experience to see the attempt made in families to analyze each individual into the aggregations or mixtures of parental characteristics manifest in them, to recognize, for example, the mother's voice, the father's passion for music, the mother's eye or the father's bony frame-work. But scientific students of heredity teach us that such an analysis, while true, since the various characters are transmitted independently, misses the most important point; namely, that in each of his qualities an individual is double. To understand really the make-up of an individual it is necessary to know how each of the two original germ-cells which united to give rise to him was endowed, as regards the factors concerned in voice, skeleton, musical faculty, color, hair and other characteristics. In analyzing the inheritance of a human being, therefore, we have to consider the contribution of each of his parental germ-cells separately for each quality or faculty; in other words, it is not sufficient to make a single column of values for the ingredients that go to form a man, but, as Bateson suggests, we must rule two columns, one for the ovum from the mother and one for the sperm-cell from the father, and in each column we must indicate how that germ-cell was supplied in respect to each of the ingredients in the list. Now, it will be clear that the male and female germ-cells may make the same or different contributions as regards any of the ingredients. When the two cells yield the same contribution the organism which results is said to be *pure-bred* for that ingredient; on the other hand, when the contribution from the two parent cells is dissimilar, the organism which results is said to be *cross-bred*. This is one of the most important conclusions to which studies of heredity has led.

From what I have said it will be clear that an individual according to our present views of heredity, is made up of a large number of distinct ingredients or units contributed from two sources and that as regards any one of these units he may have inherited two similar portions or two dissimilar portions.

To proceed with the analysis, I think I cannot do better than adopt an illustration used by Bateson in his popular address. He imagines the contents of a germ-cell as a fluid, made by taking a drop from each of a definite number of bottles in a chest containing tinctures of the several ingredients. Thus the male germ-cell is supposed to be compounded from one chest of bottles and the female germ-cell from a corresponding set of bottles in a similar chest. Should one or more of the bottles be empty in either chest then the germ-cell receives no ingredient from that chest; if corresponding bottles should be empty in both chests then neither germ-cell contains the ingredient concerned and the new individual resulting from the union of the two germ-cells by mixing the two collections of drops together would not contain the missing ingredient at all. It is obvious that an individual may be pure-bred (that is to say, similar on both sides of his composition) for any particular ingredient in either one of two ways; he may have received the ingredient from both the male and the female chest, or he may have received it from neither. Again, he may be cross-bred in respect of any single ingredient or unit, receiving the presence of it from one germ-cell and the absence of it from the other.

Having got this far, we can now conceive of the individual as composed of what are called presences and absences of all the possible ingredients. Hurst's studies of the eyes of parents and children happily illustrate this point. It appears that people have blue eyes when a factor or unit which forms pigment on the front of the iris is absent. If both parents of a child have blue eyes the children will not have dark eyes, for a dark eye has been shown to be due to either a single or a double dose of the unit missing from the blue eye. This is why dark-eyed persons may have children who are all dark-eyed or who are dark-eyed and light-eyed in certain proportions which, on the average, are definite.

The long hair in angora cats or in guinea-pigs seems to be due, not to a factor added to short hair, but rather to the absence of a unit which stops growth in short-haired animals.

It is too early as yet to offer any opinion as to the actual nature of the factors we are now talking about. Some time we may know really what they are, but as yet we are in ignorance.

PRINCIPLE OF SEGREGATION OF UNITS

Having described the formation of an individual from units brought into him by the two germ-cells derived from his parents, we may now turn to an examination of the mode of formation of the germ-cells which are formed in him himself and which will be concerned in his contribution to his children should he have them. It will be interesting to see how the various ingredients of which he himself was originally compounded are distributed among the germ-cells which are budded off from him. The observations which have been made teach that except for rare variations the germ-cells formed from him are all alike in respect of those units of which he is pure-bred. This might have perhaps been expected, but the constitution of his germ-cells in respect of the units of which he is cross-bred—I mean those units which he received from the germ-cell of one parent and not from that of the other—could scarcely have been foreseen. In the cases thus far studied experimentally in animals and plants some of the germ-cells from such individuals contain a representation of the unit and others do not, just as the parent germ-cells did or did not contain it. This fact, known as the principle of segregation of units (or determiners), is the most important discovery made by Mendel.

We now see that if a certain *unit* were brought in by both parent germ-cells, then all the daughter germ-cells have it; if it did not come in through either parent germ-cell, then no daughter germ-cell will have it; if it came in through one parent germ-cell and not through the other, then about half the daughter germ-cells will have it and about half of them will not. In other words, the individual made by the mixing of tinctures from two chests of bottles sorts the tinctures back again into a double row of bottles, a pair corresponding to each ingredient or unit, and each of the germ-cells budded off from him receives a drop from one or other bottle of each pair. This is what is known as the purity of germ-cells. "They are pure in the possession of an ingredient or in not possessing it; and the ingredients or factors, as we generally call them, are units because they are so treated in the process of formation of the new gametes and because they come out of the process of segregation in the same condition as they went in before fertilization." (Bateson.)

TYPES LIMITED

Two given parents can therefore produce only a limited number of types of offspring; the relative numbers of the types thus produced by recombinations of the parental units can often be predicted according to simple mathematical rules.

If we could know the unit characteristics which both parents possess as well as those which they both lack, and also the unit characters in which they differ, and if we further knew for each characteristic whether it was due to a presence or an absence, we could go far toward predicting the result of a particular marriage. Of course we are as yet only on the threshold of such knowledge. It is often very difficult to tell whether a parent possesses a given factor or not, but for some characters it is quite easy and can be told at once, since there are factors which cannot be present in an individual without manifesting their presence. In some families, for example, a certain number of the members are affected by night-blindness. If an individual affected marries one unaffected, their children will be partly affected and partly unaffected, but their unaffected children in turn, not containing the unit responsible for night-blindness, cannot pass it on.

COMPLEMENTARY UNITS

Through the study of pedigrees, but more particularly through experimental studies, our knowledge of Mendelian heredity is slowly progressing and very astonishing answers are being obtained to the questions which scientists are putting to nature.

Certain bodily characteristics seem to depend, not on a single ingredient or factor, but on the combined activities of several factors—the so-called *complementary units*. Thus in mice, if only one color factor is present the fur is chocolate; if another factor in the series be added the fur becomes black, and if a third factor concurrently act, the fur has the brownish-gray color of the common wild mouse.

INTERACTIONS AND REPULSIONS

Students of heredity have also found that units of different nature sometimes interact with one another during cell division. There seem to be, for example, mutual repulsions among Mendelian units, and if an individual is cross-bred in respect of two repelling factors, that is, if he has received only a single dose of each, then the germ-cells budded off from him are so composed that each contains one or other of the two repelling factors; not both. This fact has been beautifully demonstrated by the studies of Bateson and Punnett on the hybridization of sweet peas.

HEREDITY AND DISEASE

Observations on human beings show the importance of studies of heredity, not only for the understanding of normal life, but for obtaining an insight into the prevalence of abnormalities and of disease. In some families the hands have short fingers, each digit having only two instead of three phalanges.[1] The abnormality appears to be due to the presence of a Mendelian unit which inhibits the normal process of growth in the fingers. A short-fingered person married to a normal person will have children all or half of whom are short fingered; should two individuals, however, even though derived from short-fingered strains, be themselves free from short fingers, their child will be normal. The same rule in all probability applies to diabetes insipidus.

Sometimes an abnormality or a disease is due to the absence of a Mendelian unit rather than to an abnormal presence. In some families the lining membrane of the eye undergoes a pigmentary form of degeneration. Here not only members of the family affected with the disease may transmit the disease to offspring, but even those with good eyes may have children suffering from the pathologic change. The same is true of deaf-mutism. In the disease of the eye just spoken of and in deaf-mutism it is exceedingly dangerous for an affected person to marry a blood relative even if that relative does not suffer from the same defect.

IMBECILITY

Imbecility, in certain of its forms, appears to be due to the absence of some definite simple factor. If two imbeciles marry, even though they be unrelated to one another, the offspring are all imbeciles. I need only refer to Barr's case in which an imbecile of thirty-eight married a delicate wife and twenty years later was the father of nineteen defective children. Davenport states that he can find no case on record in which two imbecile parents have produced a normal child, and yet thousands of children are born every year in this country of imbecile parents. One can only think it will not be long, in view of this, before imbeciles will be restrained from reproducing their kind. The family of hereditary ataxics studied by Dr. Sanger Brown, the brains of two members of which I have studied and made a report on, illustrates well the baneful propagation of a bad stock.[2]

If time permitted statistics could be given regarding the insane, the epileptic, the chronic inebriate and the habitual criminal which would convince anyone that such persons should never become parents, and would cause to be initiated a movement to awaken public opinion and legislative action in these matters.[3]

RESISTANCE TO DISEASE

While studies of heredity show us the direction in which we must work on the negative side, they are also full of promise on the positive side. One of the most fascinating investigations with which I am familiar is that of Biffen[4] which led to the demonstration that the power to resist a disease may depend on the presence in a germ-cell of one of the simple Mendelian units to which I have been referring. It has long been known that certain kinds of wheat are very susceptible to a disease known as wheat-rust which is due to an infection with a fungus. Certain other varieties of wheat are immune to this rust disease. If an immune strain be crossed with one which is not immune, the resulting hybrids are all susceptible to rust, but when such hybrids are permitted to undergo self-fertilization they yield seeds from which appear susceptible and immune plants in the ratio of 3:1. This little experiment gives an entirely new and precise significance to what we have hitherto designated as resistance to disease; it is conceivable that a field of research has here been opened up which may yield results of great practical as well as theoretical value. It is quite conceivable that what has been found to be true in this case may turn out to be true of resistance to many other diseases in both plants and animals; and who knows but that before long the attention of medical science will be turned less than at present towards modes of infection and more than now toward the breeding of a race with heightened resistances? Indeed it seems now far from being impossible "that liability to a disease or the power of resisting its attack, addiction to a particular vice or to superstition," may be found to be "due to the presence or absence of a specific ingredient and that these ingredients are transmitted to the offspring according to definite predicable rules."

APPLICATION OF EUGENICS TO RACE CULTURE

The science of eugenics aims to make use of all these newer facts of heredity as well as those resulting from statistical or biometric inquiries, and to apply them in race culture. It will not, however, neglect the very important influence of environment, and must pay especial attention to the rôle of racial poisons like alcohol, lead and the toxins of syphilis. Time will not permit me to dwell on the obstacles in the way of eugenic progress, nor can I even refer to all the methods proposed by those who harbor the eugenic ideal. It seems to me important, however, to point out that certain of the methods recommended by enthusiasts for the improvement of the race would, if resorted to, be likely to be more harmful than useful. It seems to me probable that the new facts of heredity may be applied best through the utilization of the institution of marriage. I do not think it probable that any method incompatible with marriage, with the love of the sexes, or with the care of the children chiefly by their own parents, will be adopted at any rate in the near future. The suggestions of Plato, of Malthus, of Spencer and of Nietzsche, though important in certain directions, were all fallacious in others. It is highly probable that some of the views most generally held to-day will not bear the test of time, but, despite this, we have enough certain knowledge to permit us to do much toward the elevation of mankind by eugenic methods. Though the birth-rate is decreasing, the population of the world is increasing. Though one-third of the infants born die within five years, great strides are being made in the prevention of infant mortality. It is not necessary to foster infant mortality in the hope of removing the unfit. It is much more important to prevent the birth of the unfit. By understanding Nature and obeying her we shall learn to command her. Most of the illegitimate children now born die soon after birth. The majority of undesirable citizens do not propagate their kind, even under our present social arrangements. Selection by marriage, faulty as it is, has on the whole favored the improvement of the race. Women are becoming freer to choose husbands than ever before and social opinion regarding the length of time of engagements and the prevention of unfit matings is becoming ever more enlightened. It might be advantageous if women especially suited for motherhood were made financially independent by the state. So-called codes of honor found to be wrong are being abandoned. More and more provision is being made for the permanent detention of inebriates, insane, the feeble-minded and criminals; parenthood will be more and more prevented among these degenerate individuals, by permanent detention, or possibly, as has been seriously recommended and practiced by some, by surgical or x-ray sterilization. Young people are being educated better than before as to the significance of sex and the responsibilities of parenthood, of the dangers of racial poisons, and especially of the risks of venereal disease. With the help of the Wassermann reaction it is now possible to find out whether an individual who has once had syphilis has been sufficiently treated to prevent his transmission of the disease to a conjugal partner or a child.

HEREDITY NOT A BUBBLE

One fact is outstanding; heredity is *not* a "mere bubble to be pricked," despite the cleverness of Mr. Bernard Shaw. Through our knowledge of its laws we shall be able to progress toward the better part of the ideal of Nietzsche, who longed for the highest perfection of man. As a practical advisor for the attainment of this perfection Nietzsche may not have been wise, but no one could have had a higher aim. Thus spake Zarathustra: "Hitherto all things have brought forth something better than themselves, are you going to be the ebb of this great tide? Man is something that is to be surpassed. Thou, the victorious one, the self-subduer, the commander of thy senses, thou shalt build better than thyself. But thou must thyself be built square in body and soul. Thou shalt create a higher body, a prime motor, a self-rolling wheel; thou shalt create a creator."[5] Similar views have been expressed by one of the greatest of our American poets. What could be more eugenic than this striking passage?

> Lead the present with friendly hand towards the future—
> Bravos to all impulses sending sane children to the next age!
> But damn that which spends itself with no thought of the
> stain, pain, dismay, feebleness, it is bequeathing! . . .
> I see tremendous entrances and exits, new combinations, the
> solidarity of races—
> Always a nonchalant breed, slightly emerging, appears on
> the streets,
> Arouse, for you must justify me!
> Not to-day is to justify me and answer what I am for,
> But you, a new brood . . . greater than before known . . .
> Great idea, idea of perfect and free individuals!

EUGENICS SHOULD BE STUDIED

Fragmentary as has been this presentation, I trust that it may stimulate thought regarding the eugenic ideal; I hope that the subject will be studied and that people may become instructed in it. In becoming thorough eugenists, we shall act in accordance with the highest aims and purposes of all persons interested in true social hygiene. Though the old doctrine of predestination gets new support from the recent studies, these studies also teach us how mankind can control its destiny. It will be absolutely necessary to attack the problems of (?) the improvement of races and families and (?) the extinction of hereditary disease in the one single way in which permanent betterment is possible. We must more consciously control the union of germ-cell qualities, and we can do this by creating new sentiments regarding marriage and parenthood. In these problems lie, it seems to me, the most important and the most difficult tasks now confronting families, nations and the human race!

A STUDY OF TRANSILLUMINATION *

PERCY FRIDENBERG, M.D.
NEW YORK

The data presented in this paper were gained by clinical observation of a large number of normal and diseased eyes in adults, children and infants, transillumination of enucleated globes in the rich and varied collection of the Pathological Laboratory of the New York Eye and Ear Infirmary, and experiments with globular artificial eyes filled with blood, serum, fibrin and various colored fluids. In the last two categories, the possibility of controlling and proving the facts determined during transillumination was of great practical value. The results were such as to corroborate, in the main, what clinical ophthalmology has taught us in regard to the optical reaction of various intra-ocular structures to light transmitted through the sclera; yet a number of instructive and interesting as well as novel exceptions were encountered which will be considered somewhat in detail later.

Both the Sachs and Würdemann lamps were used throughout; the examinations being conducted in a dark room and sometimes exclusion of light was further effected by the use of a black rubber sheet over the head of the examiner and subject. Examined in this way, the normal sclera was always found to be uniformly translucent, something like the web of the fingers when held up to bright light.

In enucleated eyes this trans-scleral glow clearly outlined the entire globe and appeared at the pupil as a *bright red reflex*. The latter was most intense when the transilluminator was placed at the posterior pole, and the rays came directly forward toward the eye of the observer, or when it was placed over the ciliary body, and the pupil inspected obliquely from the opposite side. The latter is, of course, the only way in which bright illumination can be obtained *intra vitam*. The cornea offers, as might be expected, no obstruction whatever to transmitted light. It is somewhat surprising, however, that corneal opacities, no matter where situated or how dense, seem to melt away and give passage to a bright glow. Old leucomata can be transilluminated with ease, allowing us to make out the position and topography of the pupil.

Dense pannus, of recent formation, tends to obscure the reflex slightly. This is probably due to the presence of blood in the newly formed corneal capillaries, as old, obliterated blood-vessels have no such effect. Deposits of uveal pigment on the cornea, as elsewhere in the eye, act as an absolute barrier to light from the transilluminator, so that we have in this instrument a very effective means of differentiating fibrinous or purulent deposits from those containing chromatic granules. The lens, whether clear or opaque to oblique illumination, is absolutely transparent to transillumination, so that not only nuclear, polar, cortical and capsular opacities, but mature senile cataract, as well, seem to have disappeared. In siderosis affecting the lens I have observed some dimming of the light, but this was by no means marked. Cataract, accordingly, offers no obstacle to the detection of an intra-ocular tumor, or possibly of a foreign body, by transillumination.

The true stop or diaphragm for transmitted light is the pigment in the uveal layer of the iris and ciliary body. That in the chorioid is so scattered as not appreciably to affect the rays. The normal iris is absolutely opaque. I have not been able to find any difference between light blue or gray and brown or black eyes, in this respect, nor is there any appreciable difference between the dense ciliary body and the thinner iris. Uveal pigment deposits on the lens, similarly, obstruct the light and appear quite black, no matter how small or thin. In many diseased states of the iris the pigment layer disappears and the light then comes through the stroma of this tissue as brightly as it does through the clear pupil. In many cases of atrophic iris, as in chronic glaucoma, there is a marked reticulation with the appearance of cribriform or accessory pupils.

Secondary membranes after cataract extraction obstruct the light only when they contain dense blood-clot or uveal pigment. In recent intra-ocular hemorrhage there is slight dimming of the light, and a blood-clot entirely arrests it. This was seen most unmistakably in old subretinal hemorrhage and in organized clot in the vitreous. Detached retina is absolutely transparent.

The differentiation of this condition from intra-ocular tumor, particularly from sarcoma, is one of the most important applications of transillumination. As is well known, melanosarcoma casts a dense shadow. This may often be seen as a dark area at the site of the new growth, as well as by dimming of the pupillary glow. It has been claimed that unpigmented sarcoma does not show by transillumination, but at least in one instance I was able to disprove this statement by eliciting a very manifest shadow over a deep-seated leucosarcoma of the chorioid. In the absence of any macroscopically evident pigment—the tumor appeared as a dense white mass—we must assume that the irregular arrangement of tissue cells is sufficient to obstruct the passage of light. Translucent or transparent structures, such as the sclera, cornea and lens, are composed of tissue elements arranged parallel and at right angles to the rays of light which traverse them. An irregular arrangement will naturally obstruct light to some extent even if no pigment be present. Glioma of the retina is always transparent, but the presence of bony or calcareous changes is invariably indicated by opacity.

Transillumination gives no indication whatever of the circumlental space. The annular bright area immediately beyond the limbus depicted in the article by Würdemann is due to light rays which traverse the anterior chamber and come through the thin sclera about Schlemm's canal. It is only seen when the transilluminator is applied obliquely and well forward. When the light comes from the rear, the circumlental space disappears completely in spite of brilliant transpupillary reflex. Again, the appearance and dimensions of this light ring are unaltered by gross changes which not only

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910

alter, but completely abolish the circumlental space. Thus, in aphakia, there is no appreciable difference in the light ring from that seen in normal eyes. In buphthalmos and staphyloma of the cornea, the light ring may be seen to depend directly on the dimensions of the anterior transparent segment.

As the lens itself is quite pervious to light rays and, as we have seen, allows the brilliant reflex to pass through it even when completely cataractous, a delimitation of any circumlental space must be an optical, and hence, literally, a physical impossibility. Furthermore, the iris and ciliary body act as an absolutely impassable barrier extending from the pupil to the region of the ora serrata, so that no space within these limits could become visible externally. The comparison of a large number of glaucomatous eyes, before and after operation, with normal globes in patients of corresponding age has failed to reveal any differences whatever in the circumcorneal light ring.

In addition to its well-known uses for the detection of intra-ocular tumors and their differentiation from detachment and optically similar conditions, transillumination gives important information in many cases in which ophthalmoscopy is impossible, and oblique illumination alone teaches us little. This applies particularly to conditions associated with dense opacity of the cornea, such as staphyloma, extensive leucoma and occluded pupil. In dense leucoma with adherent iris, the size and shape of the pupil and the extent of its mobility under a mydriatic can be determined accurately. The site of an optical iridectomy, or the advisability of tattooing a corneal leucoma, may be determined in the light of transillumination.

This method may be combined with ophthalmoscopy for the examination of the ora serrata and neighboring ciliary region at present inaccessible on account of insufficient illumination due to the extreme angle of tilt which it is necessary to give to the ophthalmoscope mirror. With the combined method the structures far forward are seen beautifully.

60 East Fifty-eighth Street.

ABSTRACT OF DISCUSSION

Dr. Edward Jackson, Denver: The statement of Dr. Fridenberg that "transillumination gives no indication whatever of the circumlental space," is absolutely correct, and it is strange that the idea of such a connection ever gained credence. As I demonstrated before the Colorado Ophthalmological Society, at its meeting in December, 1908 (*Ophth. Rec.*, March, 1909, p. 128), the principles of optics render any connection of the circumlental space with this circumcorneal illumination impossible. The simple experiment shows that when the source of transillumination is back of the ciliary region no circumcorneal illumination occurs. Only when the tip of the transilluminator is brought forward, so as to light up the limbus on one side of the cornea, does the circumcorneal illumination appear on the opposite side. The circumcorneal ring is influenced by the absence of the lens, its dislocation or partial dislocation, or its congenital smallness.

Narrowing of the circumlental ring in connection with glaucoma does, I believe, occur. In an address before the Buffalo Ophthalmological Club a year ago (*Am. Jour. Ophth.*, December, 1909), I pointed out that this narrowing was associated with diminished depth of the extreme angle of the anterior chamber. It may also indicate sclerotic changes in the tissue surrounding Schlemm's canal, or pigment deposits in this region. Such narrowing certainly occurs in some cases of glaucoma. Possibly it may have significance as an indication as to the operation of choice in a given case of glaucoma, whether or not iridectomy is likely to give relief.

Dr. R. D. Gibson, Youngstown, O.: At the meeting of the American Medical Association in Boston I called attention to a form of transilluminator that I had to extemporize for the work we are often called on to do—the location of a foreign body. The tip of the illuminator was curved and had the lamp bulb in the end. This point can be inserted through a wound and the entire interior of the eye can be illuminated, or the point can be passed into any cavity. At the Boston meeting Dr. Würdemann, who followed me, presented his instrument, which is exactly the same, except that the light globe is placed at a different point. It is a handy instrument for emergency cases.

THE QUESTION OF ENUCLEATION IN PURULENT PANOPHTHALMITIS

WITH A BRIEF EXPERIMENTAL STUDY OF THE SUBJECT *

ROBERT L. RANDOLPH, M.D.
BALTIMORE

According to Becker,[1] forty-three cases of meningitis after enucleation of the eye had been placed on record up to 1888. The first two of these were reported by von Graefe at the Heidelberg Ophthalmological Congress in 1863, and he took occasion to warn against enucleation when the eye was in the active stage of an acute purulent panophthalmitis. With the exception of the contributions of Andrews[2] and George C. Harlan,[3] little or nothing on the subject has appeared in this country. The contributions of Leber and Deutschmann,[4] in Germany, are well known and are referred to by Andrews in his paper. Within the past twenty years, then, there has been no discussion of this interesting and practical subject, and I think that it is the first time that it has been brought before this Section. Since the above reports, others of a similar character have appeared now and again, as, for instance, that of de Lapersonne,[5] who reported a case in which the meningitis was due to the pneumococcus which was found in the sheath of the optic nerve and also at the base of the brain.

Some years ago a colleague of mine had a distressing experience with one of his patients, a child, who was struck in the eye by a piece of glass. Iridocyclitis followed and later panophthalmitis. The eye was enucleated, and three days later meningeal symptoms showed themselves and the child died. The utmost care was employed in the course of the operation and nothing was left undone which might have averted such a result. I recall a number of cases of purulent panophthalmitis in the hospital service of the late J. J. Chisolm. Prompt enucleation was the routine treatment with him for this class of cases, and I have seen some shocking looking eyes removed in the active stage of a purulent panophthalmitis and never with bad result, certainly not with fatal result. I must say, however, that I have no way of determining whether any untoward symptoms developed immediately after enucleation, symptoms which might be explained by a mild meningeal inflammation and which disappeared just as they sometimes do, without being sufficiently suggestive to alarm the surgeon or even to attract his attention. It seems to me important that those who make a habit of enucleating eyes in the active stage of a purulent panophthalmitis should keep such patients for several days after operation under the closest observation, with special reference to temperature and symptoms generally suggestive of meningeal involvement. It is quite possible for a mild meningitis to exist for a short time without being detected. It has been my rule to watch the temperature of all patients after enucleation, and I think I can say offhand that no temperature elevation followed. I speak now of eyes in which the inflammation was apparently confined within the eyeball. The conditions are different, however, when we consider an eye which is tense, full of pus, protruding and surrounded by engorged tissues, and generally this has been the picture presented in cases in which death followed the enucleation. It is in the hope of bringing out a full discussion that I bring the subject before this Section. It may be of interest to refer to discussions of this question before other gatherings of ophthalmologists. In 1888[6] the subject was up for discussion before the French society of ophthalmology. While Panas, Dufur, Motais and Gayet favored enucleation in these cases, Meyer, Galezowski and Abadie raised their voices against this procedure. According to Andrews, the late C. R. Agnew expressed himself as opposed to enucleation. In a discussion before the Ophthalmological Society of the United Kingdom,[7] Dr. Brudenell Carter, Mr. McHardy and Mr. Gunn favored enucleation, while Nettleship, Higgins and Mules were opposed to enucleation in such cases. It is evident from all this that there is much difference of opinion among able men on this point.

H. D. Noyes, in his text-book, states that from 1868 to 1888 there were 1,164 enucleations at the New York Eye and Ear Infirmary, and, of these, purulent panophthalmitis was present 161 times, and there was no fatal result. It is clear that one can practice enucleation in panophthalmitis a great many times without disaster; but when death has occurred it has nearly always been where the enucleation has been performed in the presence of a purulent panophthalmitis, especially when associated with great phlegmon of the orbital tissues. It would be interesting to get statistics of meningitis in those cases in which the eye had not been subjected to surgical interference. Cases of this character exist, as reported by Webster.[8]

EXPERIMENTAL DATA

The following experiments were undertaken to ascertain whether meningitis could be produced in some of the lower animals by first producing a purulent panophthalmitis and then removing the eye in the active stage of the disease. The animal was always etherized. The only instruments employed in the earlier experiments were a small hypodermic syringe and fixation forceps, which were boiled before using. The following case is an illustration of the behavior of the rabbit after operation, though in this, the first case, the animal died two weeks after enucleation:

Rabbit 1.—The eyeball was pulled forward and downward and the conjunctiva was dissected away, leaving the sclera bare at a point about 2 mm. behind the lens. Five minims of a suspension of *Staphylococcus aureus* were injected into the vitreous. The next day the anterior chamber was cloudy and the eyeball was intensely red. On the third day there was a typical picture of purulent panophthalmitis so the eye was enucleated. The animal declined and died two weeks later but the autopsy showed nothing abnormal in the brain.

Rabbit 2.—Jan. 17, 1909, a rabbit was inoculated in the same way and in three days purulent panophthalmitis was present. The eye was enucleated on the fourth day. The effect of the operation was negative and the animal died five weeks later from an injury received in transferring it from one part of the building to another.

Rabbit 3.—Feb. 2, 1909, I inoculated the right eye of a rabbit just as in the other two cases. The reaction seen next day was positive but less pronounced than in either of the preceding cases. There was cloudy vitreous with pericorneal redness. The condition subsided in large measure in a week, that is to say, the redness disappeared. Another injection was made in about the same place and this was followed by a sluggish inflammation of the retina and chorioid, leaving a picture which was strongly suggestive of the so-called pseudoglioma. Inasmuch as the organism employed seemed to have lost its potency through age, I injected a culture of the same organism of a 48-hours growth. This was followed by an intense panophthalmitis and on the third day the eye was enucleated. The experiment was negative.

Seven rabbits were treated in this manner and with the same result, and with the exception of the two mentioned all were living and well two months after the experiment.

Six guinea-pigs were subjected to the same experiment and the result in every case was negative.

Another series of experiments on rabbits was commenced. Instead of injecting a suspension of organisms an infected foreign body was introduced into the vitreous and allowed to remain there. The foreign body selected was a tack 1/4 inch long. A small incision was made in the usual location with a Graefe knife and the tack was pushed in with a pair of delicate forceps. Three of the tacks had been smeared with a pure culture of *Staphylococcus albus.* On the second day there was always iridocyclitis and on the fourth day typical panophthalmitis. The eye was enucleated at the height of the inflammation. Seven rabbits were treated in this manner and the result was negative in every case.

A new series was commenced and instead of using aseptic precautions the conditions surrounding the usual every-day accident were present. In six rabbits, a small piece of rusty wire 1/8 inch long was introduced into the viterous and in two rabbits a No. 5 shot. In every case purulent panophthalmitis followed and enucleation apparently had no effect on the health of the animal. In nine other rabbits particles of iron, pieces of glass and small fragments of copper wire, just the things which we see produce such disastrous results in human beings, were introduced and the results were negative. Generally speaking, the animal was a little depressed on the second and third day after operation (injection), but this had passed away by the time the enucleation was performed and with the exceptions noted were all alive and well after six weeks when the experiment was regarded as negative.

Thinking that a mild meningitis might be produced by experiments of this character and disappear without causing noteworthy symptoms six rabbits were killed at periods ranging from three to eight days after enucleation and cover slips from the surface of the brain were examined for pus cells and a piece of the brain was cut in each case from near the chiasm, hardened and examined, but there was no evidence of infection having found its way to the brain.

The results of these (43 in all) experiments tally precisely with what happens in human beings under similar circumstances, and they help to impress us with the fact that death from meningitis induced by enucleating an eye in the acute stage of a purulent panophthalmitis is an exceptional event. That the infection travels by one or more of several routes (i. e., by the lymph and blood passages, the sheaths of the optic nerve) is probable.

Yet it is my practice to abstain from enucleation, notwithstanding that the evidence speaks for its comparative freedom from risk. I always make two crucial incisions in panophthalmitic eyes, one on the external side of cornea about a quarter of an inch from the limbus and a little below and parallel to the equator of the eyeball, and another incision in a corresponding situation on the opposite side of the cornea. I have had a conviction that to enucleate such an eye was a risk, in spite of what

---

7. Trans. Ophth. Soc., United Kingdom, 1887.
8. Trans. Med. Soc. State of New York, 1888.

Panas, Mr. Gunn and others say to the contrary, and I strongly hoped to be able to prove this by my experiments. The panophthalmitis which is experimentally produced does not differ apparently in the slightest degree from the process seen in human beings, and, while experiments of this character on rabbits (which are unusually resistant) cannot be regarded by any means as very strong evidence that the procedure is a safe one, it must be conceded that such results coincide with the views held by many ophthalmologists, that the risk, if any, is too slight to be considered.

In conclusion, let me say that, in spite of the experimental and statistical evidence in favor of the comparative harmlessness of enucleating a panophthalmitic eye, I am of the opinion that incisions in the eyeball constitute a measure which is perhaps safer, and I should perform enucleation only as H. Knapp suggests in cases in which a speedy and painless recovery would be of high importance, as, for instance, in old and enfeebled persons.

816 Park Avenue.

ABSTRACT OF DISCUSSION

Dr. L. Webster Fox, Philadelphia: Being situated in a manufacturing city I have had an extended experience in enucleation of the eyeball. From the different mechanical shops we have various panopthalmic conditions to deal with. Iron workers who lose their eyes by accidents with hot metal rarely have panophthalmitis, but we find many cases among brass and copper workers. In cases in which we cannot perform the substitute operations we enucleate if pus has formed and there is destruction of the interior coats of the eye. I have not command of the statistics and do not know how many such cases I have encountered, but I have had sufficient to know that I would never hesitate to enucleate in an acute case of panophthalmitis. I have never had a case of associated meningitis follow any of these cases. Meningitis would seem to be sure to follow some of these severe cases of inflammation of the eyeball, especially after injuries. We do get it in metastases following gonorrheal inflammation of the joints or following a chorioiditis. I have had a number of such cases, and they almost come in the same class of cases as panophthalmitis, but the resistance of the posterior part of the eye seems to prevent the backward passing of the streptococci, and the stretching of the eyeball and the weakening of the cornea allows the pressure forward and not back; therefore the pus currents are directed anteriorly instead of posteriorly. I believe that prompt enucleation, as Dr. Randolph says, is the proper thing to do in these cases, and I do not hesitate to perform that operation when pus is present to such an extent that at the end of the third day there is enormous edema of the eyelids and the anterior chamber is filled with pus, and the cornea is already clouded.

Dr. C. J. Kipp, Newark, N. J.: I have practiced for fifty years and during that time I have enucleated every eye that presented this condition. I have never seen a case in which I regretted it. I think it is the proper thing to do under all conditions to relieve the pain, especially in working people. The trouble is thus cut short and I have never yet seen the slightest harm result from enucleation.

Dr. L. H. Taylor, Wilkes-Barre, Pa.: It seems to me that it is not a question as to whether it is a dangerous procedure, but whether it is not a more dangerous procedure not to enucleate. I have performed many enucleations in panophthalmitis and have always felt that it was my duty to perform the operation in the acute stage. I have done so without hesitation and have never seen any bad results. After reading Dr. Randolph's paper I did not have time to go over all my cases, but went over some of them and find that in the earlier years of my practice I operated in a very large percentage of the cases of panophthalmitis. I have not done so many in recent years, because I believe we do not have so many cases in proportion to the number of enucleations, but I have never yet seen a bad result following an operation under such circumstances.

Dr. C. H. Williams, Boston: I want to add my experience in one case. The patient was a man about 70, and in very good health, but with panophthalmitis. I enucleated that eye. Following that there was apparently a meningitis and the man died in about two weeks. I was unable to obtain an autopsy. That is the only case that I have ever had in which a fatal result followed enucleation, but it shows, I think, that there is a certain amount of danger—not enough to prevent the operation from being done where it seems necessary, but enough to cause us to be very careful in regard to all our aseptic methods.

Dr. S. L. Ledbetter, Birmingham, Ala.: Living in a manufacturing and mining section, I have had quite a number of these cases, but still not enough to make out a case for or against the operation. In a large percentage of cases in which I have done an enucleation I have found a rupture of the sclera and there was already pus in the tissues behind the ball. Taking that view of the case, I believe there is more danger of leaving the pus than in removing the ball and allowing drainage.

Dr. E. C. Ellett, Memphis, Tenn.: Something must be done in these cases, and of course the alternative to enucleation is evisceration. Now lest we should think this an absolutely safe procedure I should like to relate my experience in one case. The patient, a negro, was shot in the eye with a slungshot, the missile being a piece of a small iron nut. When he came to me he was sure that the missile when it struck him had fallen to the ground, and beyond a dressing of the eye nothing was done primarily. The patient developed a panophthalmitis. An evisceration was done and this body removed from the interior of the eyeball. There was no penetration of the sclera, the wound of entrance being through the cornea and wholly within the cornea. The patient developed a general septic infection and died. I did not think he had a meningitis. A culture from the fluids in the eye at the time of evisceration showed colon bacillus.

Dr. Prince, Springfield, Ill.: Ever since the publication of Dr. Wisner's article suggesting the danger of enucleation in panophthalmitis I have followed his recommendation and have invariably eviscerated. I have never had any complication from that procedure since the very earliest operations. At first I had an enormous amount of inflammation following the evisceration, but I very early learned to cauterize the inside of the stump with phenol and to fill it with iodoform. This raises in my mind two questions: One is the danger of fatality and the other is the preservation of the stump. In every case in which there is not a septic condition I introduce a gold ball for the purpose of preserving a good stump. In enucleation in some instances I believe we get almost a gangrenous process and in one case the inflammation was so severe as to produce a paralysis of the superioris muscle. I have never had a complication of the ball or lid following evisceration, and if it can be shown that we can get a better cosmetic effect I should be in favor of evisceration rather than enucleation in panophthalmitis.

Dr. S. L. Ziegler, Philadelphia: I have had many of these cases and have never hesitated to enucleate. One case, in which the result was fatal, certainly was an exception. It was a case of lime-burn following the use of a spray. The man, not receiving the effect from the spray, looked into the nozzle, and at that moment, the spray, like the gun that is not loaded, went off and the eye was filled with whitewash. This was followed by a severe inflammation. I did not see the patient until three or four days after the accident. I think that before the enucleation was decided on there were certain symptoms which indicated a very mild meningitis. The symptoms certainly appeared to be severe enough to warrant enucleation. There was in connection with this a certain amount of discharge, which may have some bearing on the ultimate result. When the eye was enucleated, and afterward, although there was more or less antiseptic dressing used, the discharge continued. In another such case I certainly would dress it as an open wound with formalin dressing, but instead of enucleating I would undertake the old-fashioned method of splitting the eyeball, allowing the inflammation to subside, and dressing it as an aseptic stump until it was in a condition for further operative procedure.

Dr. Edward Jackson, Denver: I have never seen a serious complication from an enucleation during a panophthalmitis. I have sometimes eviscerated and sometimes split the eyeball from the fear that something serious might result. I saw one case in the practice of another surgeon in which the panophthalmitis was subacute—not very severe. The eye was let alone—no operation was done—but afterward, I believe, between two and three weeks, a meningitis developed and ran a somewhat slow course to a fatal termination, although the eye had not been interfered with in any way.

Dr. Hiram Woods, Baltimore: This thing sometimes assumes importance from an economic point of view in a few cases in which men have been injured in industrial accidents, and there is something in the point of Dr. Taylor that it might be more dangerous to let them alone. In a case I saw, a man was injured in the afternoon and brought, bleeding from the nose, into the hospital late, where he was seen by the intern and cleaned up. A crowbar had gone through the left eye. The next day I found that the inner wall of the orbit was inflamed. There was no pain and the eye was wide open. The question came up whether to enucleate or withhold operation on account of the fear which Dr. Randolph has brought out in his paper, and the eye being wide open and the patient being free from pain and free drainage present I decided to let him alone. He did well for two weeks; then suddenly his temperature shot up. The intern called a consultant, and lumbar puncture was done but the man died from meningitis and a culture showed infection from the Flexner organism. The Flexner serum was tried, but without effect. Dr. Flexner wrote Dr. Wilson that it was the first traumatic case in which this organism had been found. The case resulted in a lawsuit. It occurred to me to ask myself what the result would have been if I had taken that eye out. The man was let alone because the ocular symptoms were not severe enough to make us do anything in an operative direction. He apparently contracted a meningitis from the rupture of the inner wall of the orbit.

Dr. R. L. Randolph, Baltimore: I did not want to give the impression that I was in favor of enucleating the panophthalmitic eye in all cases promptly. Such certainly was not the intention in the paper. I stated that in that variety in which there is an enormous amount of engorgement of the surrounding tissues that I always made incisions in the anterior part of the eyeball. I think it is quite evident that there is not the same diversity of opinion among American ophthalmologists as among our confrères across the Atlantic. At the same time I cannot help thinking from my reading and from the discussion this afternoon, that there is a small element of danger in removing an eye in this condition, and I still think it is the safer procedure, perhaps, to make incisions as I suggested rather than take out the eye in the active stage. The cases reported by Dr. Jackson and Dr. Woods, and I think one or two of the others, and Dr. Webster's case, in which meningitis followed, are interesting. I understand Dr. Woods to say that in his case there had been a direct entrance of the foreign body into the brain. Of course that case would be thrown out of the class of cases having an optical origin or a bearing on the question of meningitis following a panophthalmitis, because it would not be necessary to consider the eye as the source of the infection.

Mosquitoes and the Vernal Recurrence of Chorea.—In the *Woman's Medical Journal*, April, 1910, Dr. Marion Craig Potter, Rochester, N. Y., reports five cases of chorea occurring in the spring or summer, two of them recurrent cases, in which investigation seemed to indicate that mosquitoes stood in a causal relation to the occurrence of the disease. In one case the disease recurred a second and third season within two weeks after going to a summer resort where the child was severely bitten by mosquitoes. In the other cases there was a definite history of being severely bitten by mosquitoes with the development of the chorea following.

THE RADICAL TREATMENT OF LACRIMONASAL DISEASE BY RAPID DILATATION AND ALLIED MEASURES *

S. LEWIS ZIEGLER, A.M., M.D.
Attending Surgeon, Wills Eye Hospital; Ophthalmic Surgeon, St. Joseph's Hospital
PHILADELPHIA

Free drainage of the mucous-membrane-lined cavities and canals of the body is a fundamental essential in preserving their physiologic functions and preventing their infection. The radical relief of tear-duct disease presupposes, therefore, the successful accomplishment and maintenance of a patulous lumen in the lacrimonasal canal. The most important measures utilized for this purpose consist of dilatation, incision, introduction of styles, irrigation, electrolysis and cauterization. Extirpation of the lacrimal sac occupies a special field of its own and will not be discussed at this time.

ANATOMIC CONSIDERATIONS

For convenience we may roughly divide the tear-drainage apparatus into three parts, the first portion comprising the lacrimal puncta and canaliculi, the second the lacrimal sac, and the third the *ductus ad nasum*. The bony canal is lined with periosteum covered with cavernous tissue, over which is superimposed a layer of mucous membrane paved with columnar ciliated epithelium. This lining is often thrown up into transverse folds or rugæ which may be annular in arrangement and sometimes possess a valve-like action. The muscle of Horner at the upper end and the valve of Hasner at the lower end complete all the tissue elements essential to our problem.

The length of the bony canal varies from 20 to 29 mm. and its diameter has been variously estimated at from 2 to 7 mm., the average being 4 mm. Power[1] in 1885 carefully measured 551 bony canals and found that the average diameter was 3.77 in whites, 4.70 in negroes and 4.63 in Mongolians, the general average of all races being 4.22 mm. Theobald[2] in 1877 stated that an examination of 70 bony canals revealed an average diameter of 4.11 mm., while tests of muco-periosteal lined canals in the cadaver showed a caliber of from 4.47 to 5.25 mm. It is evident, therefore, that moist cadavers permitted larger probes to be passed than could be passed through the distorted bony canals of dried skulls. To go a step farther, we may naturally deduce what I have found to be a fact, that the lacrimonasal canal *in vivo* is more distensible than it is in skulls because the bones and tissues are more flexible.

PHYSIOLOGIC DESIDERATA

The normal function of the tear-duct is to draw off from the lacus lacrimalis the excess of tears collected there and to pass them freely downward into the nose. By winking and slight muscular contraction we encourage a suction or siphonic action which carries off this lacrimal fluid through capillary attraction. It should be our aim, therefore, to secure a patulous tear-duct and at the same time to preserve, so far as possible, this physiologic function of capillarity. The ideal method should accomplish this by a sudden wide dilatation of the duct without incision of the punctum or of the canaliculus.

PATHOLOGIC FACTORS

The pathogenic influence of intranasal lesions in the etiology of lacrimal disease is generaly accepted. It is estimated that at least 90 per cent. of these cases have a nasal origin. Secretions that are chemically irritating and laden with infectious bacteria are poured out from the accessory sinuses onto the floor of the nose and carried by reversed capillarity up into the lacrimonasal duct. The inflammation resulting from this irritation may be superficial, causing ulceration, stricture or catarrhal thickening of the mucosa. On the other hand, the infection may penetrate the deeper structures, resulting in periostitis, caries or even in the formation of abscess. We must always bear in mind, therefore, the possibility of two active factors in the etiology of ocular disease, first, the pus-laden nasal fluids which the tear-duct may suck up and transmit directly to the eye, and second, the perverted secretions which the obstructed tear-duct may develop within itself. I have elsewhere[3] referred to this as follows:

> If now we concede an infectious cystitis of the antrum, we can comprehend how it is possible for an unlimited stream of pathogenic micro-organisms to be poured out onto the cup-like floor of the nasal chamber, and by capillary attraction drawn up into the lacrimonasal duct, and thence to the ocular cul-de-sac. The lacrimonasal duct itself is, moreover, a most fertile nidus for this bacterial development. The presence of strictures, viscid secretions, ulceration of the lining membrane, or interstitial thickening of the same, all tend to interfere with its siphonic action in the downward drainage of the tears. The bacterial growth is greatly facilitated by the consequent stagnation. Not only are the tears prevented from passing into the nose, but microbic infection is carried upward to the eye by the regurgitation of these septic secretions.

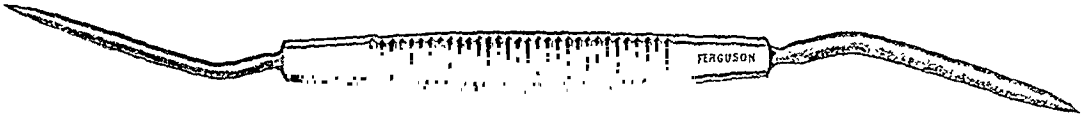

Fig. 1.—Ziegler's lacrimal dilator.

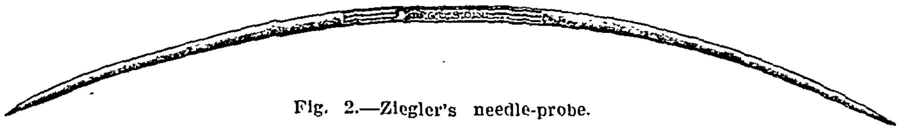

Fig. 2.—Ziegler's needle-probe.

The ocular tissues that are most vulnerable to these septic and irritating fluids are the cornea, the conjunctiva and the palpebrum. Ulcerative keratitis, especially when recurrent, phlyctenular keratitis, vascular keratitis, sloughing of the cornea and wound infection may originate in this manner. Chronic conjunctivitis, eczema of the lid, and blepharitis marginalis may arise from the same cause, while the influence of persistent lacrimal irritation in causing ectropion and entropion is well known.

The absence of epiphora or blennorrhea does not contraindicate lacrimonasal disease. On the contrary, we should always remember these two important facts, first, that we may have obstructive lacrimal disease without epiphora, and second, that we may have ocular infection without visible blennorrhea.

DILATATION OF THE DUCT

While many authorities have advocated probing of the tear-duct, Bowman probably did most to popularize this procedure. His probes, however, were very small, the largest measuring only 1.5 mm. Credit for the use of very large probes is undoubtedly due to Theobald, who in 1877 began to advocate publicly such extreme measures, and to demonstrate the excellent results which he had obtained. His probes were cylindrical in shape with a conical point, the series ranging from 0.25 mm. (No. 1) to 4 mm. (No. 16), the interval of increase being 0.25 mm. Probes of similar caliber were also adopted by Couper of London at about the same time, but were not so well accepted owing to the olivary shape of the point and the larger interval of increase (0.50 mm.).

While intern in the Wills Eye Hospital, from 1887 to 1889, I saw many patients treated with large probes in the services of Dr. Goodman and Dr. Harlan, and was greatly impressed with the superiority of this method over others in use at that time. My observations, however, convinced me that there were several disadvantages that ought to be overcome: (1) the process of dilatation was too slow; (2) oft-repeated probing created irritability of the tissues; (3) treatment was neglected by the patient because of the frequent visits required; (4) irritating nasal secretions were frequently expelled into the eye by blowing the nose; (5) the capillarity of the duct was completely destroyed by the combined Bowman's incision and the extreme dilatation secured by the use of No. 16 probes (4 mm.). The conviction was forced on me, therefore, that if a large caliber was necessary this should be accomplished at one sitting by a forcible dilatation, *ad maximum,* but without incision of the tissues, thus preserving the capillarity of the duct and avoiding the many disadvantages of the older method.

DESCRIPTION OF AUTHOR'S LACRIMAL DILATOR

I accordingly devised, in 1890, a lacrimal dilator[4] with a cylindrical body and an oval point (Fig 1), based on the old conical dilator of Levis, but essentially different in its size, shape and action. The conical dilator of Levis had three serious defects: first, it was so thin at the point that a false passage might easily be made; second, the cone in entering the bony canal became a sort of wedge that passed through the sac easily but soon became blocked; and, third, the thin point of the instrument did not properly stretch the inferior portion of the canal as it emerged into the nose. I therefore changed the body of the dilator to a cylinder, and made the point more ovoid or bellied, with a sudden widening of the caliber just above the apex. This allows it to dilate so rapidly that the point does not catch in the mucous lining of the canal, and the body of the dilator never becomes wedged as with the simple cone.

The instrument is made in the shape of a double bayonet, two sizes of the dilator being joined together on a single handle. The smaller end is somewhat sharp-pointed and has a diameter of 2 mm., corresponding to a No. 8 probe, the shaft being 28 mm. long. The larger end is more dull and has a diameter of 3 mm., which corresponds to a No. 12 probe, the shaft measuring 30 mm. in length. The maximum diameter (3 mm.) which I adopted, therefore, was sufficient to accomplish the end desired, although it was considerably less than the 4 mm. caliber exemplified by the No. 16 probe of Theobald. This dilator depends for its success on the rapidity of its dilatation, the avoidance of repetition in probing and the fact that it retains and improves the capillarity of the duct. The instrument is made of forged steel to avoid any danger of bending. A needle-probe (Fig. 2) was also devised for use in cases of atresia. The needle-probe has the same quick expansion just back of the point, which is much sharper than that of the dilator. The oval point in like manner avoids the danger of catching in the tissues. Either the needle-probe or the small end of the dilator may be used to dilate the punctum and canaliculus, but the large dilator should always be used to stretch the *ductus ad nasum.*

AUTHOR'S METHOD OF RAPID DILATATION

Anesthesia.—As the operation is somewhat painful anesthesia is required. The instillation of cocain and epinephrin into the cul-de-sac may prove to be sufficient. These solutions may also be injected into the duct through the small cannula of the lacrimal syringe, or, if preferred, with the hypodermic syringe. As a rule local anesthesia will suffice, but nervous patients will require general anesthesia. In private practice I frequently employ nitrous oxid, but chloroform and ether may also be used for this purpose.

First Stage.—If local anesthesia has been used the patient may be seated and his head covered with a towel. For the right eye the operator stands behind the patient, whose head should rest against the surgeon's chest. With a small piece of cotton under his left thumb the lower lid is drawn down and out until the margin is tense. Holding the dilator (or needle-probe) vertically in his right hand, the small end is inserted into the punctum with slight force in order to be sure that it is engaged. A feeble click may sometimes be heard, or a sensation of sudden yielding be felt, as the punctum stretches open.

Second Stage.—Still holding the lid tense, the dilator is rotated from the vertical to the horizontal position, and slowly but firmly passed through the canaliculus, the shaft being directed obliquely upward and inward, until the point rests solidly against the bony wall of the sac. If elastic resistance is felt at this point the bony landmark has not yet been reached, and further pressure should be made. As the dilator enters the lacrimal sac a rather pronounced click may be heard, or a yielding sensation may again be felt, as in entering the punctum.

Third Stage.—The small dilator (or needle-probe) is then withdrawn from the canaliculus and the large dilator (No. 12) is inserted, as in the first and second stages, until firm bony resistance is again felt.

Fourth Stage.—The lower lid is now released from the traction of the left thumb. The point of the dilator is held snugly against the bony wall while the shaft is again raised 90 degrees to the vertical position and half rotated on its long axis until the shoulder of the bayonet is turned backward. Still hugging the bone the point of the dilator describes a half-curve backward and downward as it slips over the bony ridge of the lacrimal crest and engages in the sac. It is then pushed with firmness and considerable force, downward and slightly forward, through the nasal duct into the nose. The bayonet shape of the shank allows this to pass without pressing against the eyebrow. The dilator is allowed to remain *in situ* for a moment (or longer if desired) and then withdrawn directly upward.

MINOR ACCIDENTS

A small rupture of the punctum may occur, but this is insignificant and usually heals promptly.

There may be some ecchymosis or even swelling of the lower lid, but this soon disappears.

The nose frequently bleeds for a few minutes owing to a slight scratch of the nasal mucosa by the point of the dilator as it emerges beneath the inferior turbinate.

Patients should be warned not to blow the nose for twenty-four hours, as a very slight rupture in the lining of the canal will permit a palpebral emphysema that might prove alarming and unsightly, although it will disappear spontaneously in a few days.

Irrigation should not be attempted for at least one week, as part of the fluid might escape through some minute laceration of the lining membrane and thus cause infiltration of the tissues.

In a few cases I have noted a crackling sound that indicated slight fracture of the bony walls of the duct, but I can only agree with Theobald in saying that nothing more serious than ecchymosis has followed.

I have often been asked as to the danger of making a false passage. I have never seen such an accident, but an ignorant, careless or unskilful operator may spoil any operation. I have encountered a few cases of caries in which the usual pressure might have caused the dilator to perforate the lacrimal bone and to enter the nose over the middle turbinate. One must always "have an eye in the point of the dilator."

POST-OPERATIVE TREATMENT

The after-treatment is usually very simple, consisting of a soothing eyewash, to which epinephrin may be added in the proportion of 1 to 16. If the eyelids are glued together for a few days following the operation an astringent application will promptly check the conjunctival discharge. If there should be any puffing of the lids ice-pads may be applied. If there is ecchymosis hot stupes are indicated. If emphysema occurs no treatment is necessary, as it will promptly and spontaneously disappear.

INDICATIONS FOR RAPID DILATATION

Rapid dilatation of the lacrimonasal duct is indicated whenever a permeable canal is desired. It is particularly effective in those cases of epiphora and obstruction arising from atresia, localized stricture and general stenosis with interstitial thickening of the mucosa. Absorption of this submucous hyperplasia will often be stimulated by the mere mechanical pressure of the instrument in the canal. The most striking success of rapid dilatation is probably shown in ulcerative lesions of the cornea, and especially those of the recurrent type. The phlyctenular variety also yields promptly to this treatment. In sloughing keratitis, however, we must supplement the dilatation of the duct by disinfecting the corneal slough with formalin (1 per cent.) and by using an antiseptic wash or spray in the nostril, either hydrogen peroxid or potassium permanganate (1 to 2,000). I do not hesitate to practice rapid dilatation in cases of wound infection (lacrimal) following operation or injury, and even after cataract extraction, thus eliminating the focal origin of the infection. In many of these cases, however, I inject formalin (0.25 per cent.) into the anterior chamber, in addition to disinfecting the margins of the wound and cleansing the nostril. This technic has undoubtedly saved many eyes that appeared to be hopelessly lost.

Rapid dilatation is also of value in cases of chronic conjunctivitis, blepharitis marginalis and eczema of the lid, in which the chemical irritation of the lacrimal fluids is the chief etiologic factor. It is likewise indicated in ectropion and entropion of mild degree arising from persistent lacrimal irritation. Contraction of the socket, with an irritating discharge and more or less palpebral disturbance, is a positive indication for this procedure. I have, for many years, performed rapid dilatation in every case of enucleation, as a routine measure, for the sole purpose of preventing any secondary disturbance that might arise from the accumulation of irritating secretions in the socket. This plan has been markedly successful in preserving a healthy socket.

I have previously discussed the treatment of trachoma[5] before this section (1897) by advocating rapid dilatation of the tear-duct to relieve corneal maceration and pannus through the free drainage of acrid lacrimal secretions. At the same time I recommended that this operation should be combined with canthoplasty or external canthotomy (cantholysis) for the purpose of relieving the friction and corneal erosion caused by the tarsal pressure of blepharophimosis. Each one of these procedures thus supplements the other.

ALLIED MEASURES

While rapid dilatation is invaluable in cases of acute dacryocystitis, mucocele, persistent blennorrhea, suppuration, abscess and fistula, certain auxiliary measures may also be necessary. Irrigation, incision, stricturotomy and the insertion of styles or medicated bougies are often indicated to meet the requirements of the symptom-complex which these cases present.

Irrigation may be practiced either before or after rapid dilatation. The injection of an astringent or antiseptic solution is always a valuable cleansing adjuvant and often a curative agent. I have devised an all-glass lacrimal syringe (Fig. 3) for this purpose, which is provided with four cannulas; a small gold cannula for introduction into the punctum; a platino-iridium hypodermic needle for local anesthesia; a Tansley cannula with lateral perforations and closed end; and the ordinary Anel or De Wecker cannula.

Schwenk secures good results by injecting liquid petrolatum into the tear-duct once or twice a week and allowing it to remain until absorbed. Following the method of treating fistulous tracts by the use of bismuth-petrolatum paste, introduced by Beck,[6] of Chicago, I have been injecting his formula modified as follows:

℞.

Formalin	1/2 part
Alypin	1 part
Antipyrin	2 parts
Paraffin	5 parts
White wax	5 parts
Bismuth subnitrate	25 parts
Petrolatum, enough to make	100 parts

Mix and make antiseptic paste.

This paste can be heated and injected into the tear-duct with the glass lacrimal syringe, in a fluid state, taking care that it shall not be forced through into the nose, and applying a small ice-bag in order to quickly harden it, *in situ*. If preferred, the compound may be used in a cold or congealed state, and forced directly into the duct by means of the cold paraffin syringe. I usually employ the latter method.

By the substitution of gelatin for petrolatum in the above compound it may be poured into moulds and hardened to form "lacrimal bougies." I have been using these gelatin bougies of formalin-bismuth and also those made with argyrol, but I have not tested them for a sufficient length of time to make a definite report on the results. I am convinced, however, that they will prove valuable. I have observed that the slower they dissolve the greater is their efficiency.

The incision of Bowman is indicated when suppuration is already established. This should be supplemented, however, by rapid dilatation. In performing Bowman's operation I prefer to use an instrument combining my needle-probe on one end and a modification of Weber's knife on the other (Fig. 4). I have shortened this knife, widened the blade, made the edge more oval and used a straighter tip. With such a combination we can stretch the punctum and slit up the canaliculus without changing instruments, which is a great advantage when we have ignorant and unruly patients to deal with.

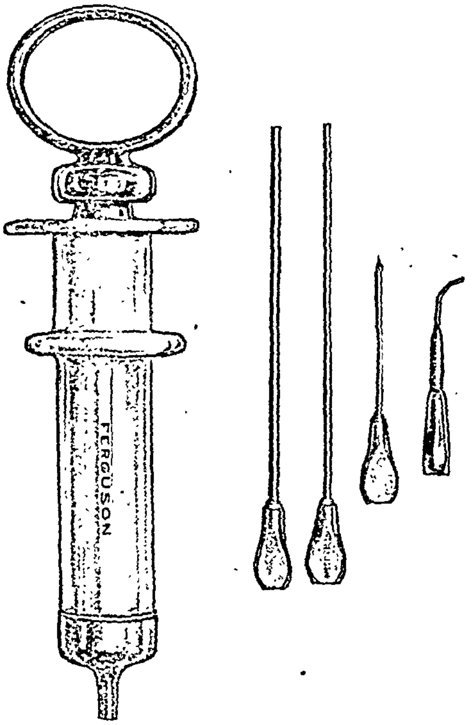

Fig. 3.—Ziegler's glass lacrimal syringe with special cannulas.

In cases of lacrimal abscess the abscess should be opened, formalin applied to its lining membrane, Bowman's incision made and rapid dilatation performed. In lacrimal fistula the same method is indicated. A lead style may also be inserted. This promotes free drainage of pus and allows the inflamed tissues to undergo normal healing, without further irritation.

It is sometimes necessary to go a step further and perform stricturotomy, after the method of Stilling, particularly in those cases in which localized bands of contraction are obstructing the canal. Instead of Stilling's knife, however, I prefer the lacrimal stricturotome[7] of Thomas (Fig. 5), which has a stronger blade than the Weber knife, is probe-pointed and has a long malleable shank. Bowman's incision is performed first, followed by rapid dilatation and lastly by stricturotomy. The Thomas knife is inserted into the duct, the probe-pointed blade is pushed down through the stricture and again drawn up, thus cutting through the stricture fore and aft; or, if necessary, four quarter-sections may be made. An application of formalin to the diseased lining of the canal is sometimes an efficient supplementary measure.

[6] Beck, E. G.: Fistulous Tracts, Tuberculous Sinuses and Abscess Cavities; A New Method of Treatment by Bismuth Paste, The Journal A. M. A., March 14, 1908, p. 868.

[7] Tr. Ophth. Sect. A. M. A., 1892, p. 235

If proliferation occurs in the lumen of the duct I employ a lacrimal curette to remove the granulomata. I have devised a small curette (Fig. 6), for this purpose, consisting of a long oval cup with teeth on the edge and a shank that is flexible but not malleable. This can be easily introduced and used with considerable pressure. The procedure is simple and the result will often prove most gratifying.

Lead styles have been popular ever since they were *first recommended by* Green[8] in 1868. They are indicated chiefly in cases of dacryocystitis, stricture of the duct and caries of the lacrimal bones. They may be allowed to remain in the duct until the lining has reformed, although they should be removed at stated intervals and the canal irrigated. Occasionally they will create irritability of the tissues accompanied by granulations and must then be abandoned for some other form of treatment.

As pure lead wire is very soft, and may bend on itself while being introduced, I have modified this by the addition of a small amount of tin alloy, which so strengthens the wire that it can be passed more readily and still retain the necessary flexibility. I have made a further modification of this wire by having it drawn with a small groove, which I think facilitates the drainage problem. I generally use the 2 mm. wire, which is the equivalent of a No. 8 probe. Lead styles have the advantage that they are cut from the solid wire and are preferable, therefore, to any form of gold or silver cannulas, which soon become filled with septic and foul-smelling secretions. They should be made perfectly smooth in order to avoid the deposit of accretions on any roughened area.

To facilitate the insertion of the lead style I have devised a pair of forceps with grooved jaws (Fig. 7) which grasp the style and hold it absolutely rigid. After the style has been introduced into the duct it can be released with the greatest ease by simply pushing the slide catch. If the style should subsequently slip down into the duct, or the tissues should grow over it, there may be considerable difficulty in locating and removing it. By using one of the small curettes, preferably with teeth, it can be gently probed for and easily removed by slipping the curette under the bent arm of the style and drawing it upward.

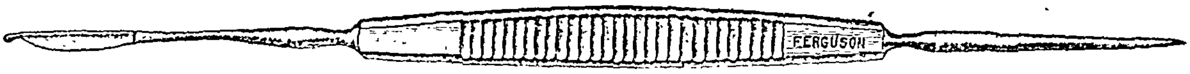

Fig. 4.—Modified Weber's knife with Ziegler's needle-probe.

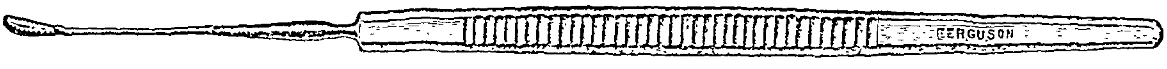

Fig. 6.—Ziegler's lacrimal and chalazion curette.

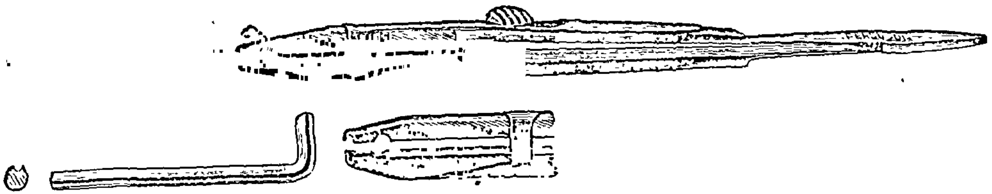

Fig. 7.—Ziegler's lead style introducer with grooved lead style.

AUXILIARY TREATMENT OF THE NOSE

We should never lose sight of the nasal etiology of tear-duct disease, and should apply our treatment accordingly. The rhinologist should remove all obstructive lesions, by reducing the hypertrophied tissues and instituting measures to restore ventilation of the upper air chambers and free drainage of the sinuses. As the anterior portion of the inferior turbinate sometimes presses on the valve of Hasner, and thus obstructs the lacrimal drainage, the fleshy fold of the turbinate should be *excised, if necessary. Temporary disinfection* of the nostril is especially indicated in all cases in which direct ocular infection is suspected.

IN CONCLUSION

Rapid dilatation of the lacrimonasal duct is by no means a panacea, but if used with judgment and discretion will undoubtedly prove a most valuable addition to our treatment of tear-duct disease. Its value lies in the rapidity of the dilatation, the avoidance of repetition in probing, and the retention of the capillarity of the duct. In some cases, however, the capillarity must be sacrificed, and in a very few cases it will be necessary to repeat the dilatation. In cases of periostitis or caries a second dilatation may be necessary, after the lining of the duct has healed. Stretching is likewise repeated in cases in which a prolonged course of nasal treatment has been instituted and completed. These cases of repetition probably constitute 1 per cent. of all cases treated. I abandoned the use of lacrimal probes nearly twenty years ago and have since relied almost exclusively on rapid dilatation of the tear-duct in order to secure the permanent patulous lumen which the radical treatment of lacrimonasal disease demands.

1625 Walnut Street.

ABSTRACT OF DISCUSSION

DR. H. MOULTON, Fort Smith, Ark.: Rapid dilatation is not a new procedure; see Juler's text-book, 1884, etc. The bivalve dilator of Galezowski is well-known. But Dr. Ziegler's method I believe is absolutely unique; first, in the pointed cylindrical shape of the dilator, second, in the fact that it is to be passed through the uncut punctum and canaliculus. The shape of the probe or dilator is ideal for its purpose. Is there ever complete cicatricial closing of the punctum after Dr. Ziegler's operation? It is often observed, I believe, that a slight abrasion of the lumen of the punctum by the point of a syringe or the moderate stretching by the pointed Weber's dilator will produce its obliteration. To dilate the punctum to a diameter of 3 mm. may have a different effect: it may so paralyze, as it were, the sphincter that it cannot shut up and grow together until the epithelium has reformed. On the contrary, when it is necessary, a clean properly made cut of the canaliculus is not harmful. I have never seen epiphora remain after such a cut when the diseased condition of the passages below has been removed. Hence, I do not hesitate to make this cut when it facilitates the treatment. How long does the effect of a dilatation last? Dr. Ziegler states that a repetition is seldom necessary; but how long a time is covered by his observation of a series of cases? His endorsement of this method is certainly sufficient to warrant any of us in trying it in suitable cases. Its painfulness, if nothing else, will probably limit its employment somewhat in private practice. I can endorse what Dr. Ziegler says of the value of the treatment of the lacrimal passages in trachoma, and of lead styles. In 1908, at Chicago, I presented a paper to this Section on the subject of lead styles. I continue to use them and the results are excellent. I do not find it necessary to have the styles grooved as does Dr. Ziegler. The drainage with the round wire is perfect; hence what is the use of a groove which might be irritating to the tissues which will certainly collapse into it. I find the fuse wire of electricians the best material of which to make these styles.

---

[8] Tr. Am. Ophth. Soc., 1868, p. 31.

DR. J. L. THOMPSON, Indianapolis: I have operated on the ducts for forty years. I at first opened the upper canaliculus instead of the lower and then resorted to styles, not like the recent and larger ones we have. I would curve them so that they hung out over the lids. We were using these styles when Theobald began using the large probes. I used them large enough, as I said at Edinburgh once, for a horse, and they would close up. I have had my poorest successes in the treatment of the lacrimal duct unless I obliterated or extirpated the sac. There was only one author who had worse success, and that is B. Kocher of London, who wrote a book on the eye some years ago and who gives one to understand that after all these trials there will be relapses in a large number of cases. In one case I put in very large lead styles and in spite of everything the duct would close. Those of you who have not practiced a long time will find that you will meet with your poorest successes in the treatment of lacrimal duct troubles of almost anything you have to deal with.

DR. DONOVAN: At the meeting of the Academy of Ophthalmology in Denver six years ago I described an operation I am still using. I opened the upper duct and cut instead of dilating. My experience in dilating with the probe has been unsatisfactory. For that reason I have used the cutting method and have had no bad results from the use of the knife and a clean incision. I start with a Theobald probe, about 6 in size, and skip two or three at a time and reach 13 or 14. No. 12 I have not found quite as satisfactory as Dr. Ziegler has. I have usually had trouble a few days later, but if I used a 13 or 14 I could then afterward use a 12 at intervals of several days covering a few weeks of time. Another method I spoke of in connection with this last year was the use of an ointment of biniodid 1 to 5,000, made by rubbing mercury and potassium iodid with hydrated wool-fat and petrolatum, and injecting it in the sac and duct. It has helped a great deal in my treatment of these cases.

DR. CHARLES H. WILLIAMS, Boston: It seems to me in a great many of the more severe forms of lacrimal sac trouble we get better results by the removal of the sac rather than by probing. Has Dr. Ziegler had trouble, from the very sharp-pointed probes described in the paper, in getting a false passage in passing such a probe?

MR. J. HERBERT PARSONS, London: I have strong opposition to probes, as expressed in papers in England, and believe that the best treatment is extirpation of the sac. I have seen the practice of various surgeons, some of whom persist in using probes, others using the method of extirpating the sac, and have had opportunity to compare the two series of cases. The results, I believe, would convince most people that extirpation of the sac is very greatly the superior method. Of course I cannot say anything about the peculiar method of Dr. Ziegler, whose probe is specially devised, and it may have special advantages which the ordinary probes do not possess; but the pain and discomfort from the probing, and the repetition of the operation which is almost invariably necessary seem to be a grave objection as compared with the slight discomfort experienced after a satisfactory extirpation of the sac.

DR. JOHN E. WEEKS, New York: I have had some years of experience in treating lacrimal stenosis and my experience with dilatation of the canal has been so unsatisfactory that I have given up largely systematic probing. Those who have had a large experience know that the dosage must be repeated frequently, and sometimes it is continued for a long period of time, as Mr. Parsons has said. I employ extirpation of the sac in all cases of chronic dacryocystitis in which the patient will submit to it. But there are a number of cases in which the patients will not submit to such an operative procedure, and I have found that I obtain satisfactory results by the use of styles, as has been mentioned. The use of lead, silver or iron styles is objectionable on account of the deposits and the corrosion in the case of silver and iron. I find that gold styles are the best. A style 1.5 mm. in diameter, which does not fill the entire canal may be inserted. The precaution to be employed is to make the style sufficiently long to have a button or hook on the upper extremity so that the style will not be lost in the canal. I have treated a number of cases with these gold styles and the results have been very satisfactory. The patient may have to wear the style a year, but three months may be enough. Then it can be removed and the canal will remain patent. The cannula should not be grooved, because the canal soon fills and the grooved have no advantage over the smooth styles. They permit the formation of a ridge of tissue which it is difficult to obliterate and which does not heal smoothly. The style should be round or oval and perfectly smooth.

DR. HIRAM WOODS, Baltimore: After Dr. Ziegler wrote his former article on the subject of phlyctenular conjunctivitis, keratitis, chronic forms of conjunctivitis and blepharitis as possibly due to reinfection of the lacrimal sac from the nasal passages, emphasizing the view that epiphora is not a diagnostic mark of such lacrimal infection, I began to look into that alleged fact with reference to some of the inexplicable chronic inflammations, and that led to my first use of the smaller one of the probes he has shown here—the opener. I was surprised to find, in the first place, how easy it was to introduce that through the punctum and canaliculus, making way for the use of a 2, 3 or 4 Theobald probe, and how frequently such patients recovered without any splitting of the canaliculus at all, but by simply making the first opening with the Ziegler probe and following it with small probes and the irrigation of the sac. That is one class of cases in which I find the Ziegler instrument extremely useful. The dilatation of the punctum preserves the siphon-like action, while splitting destroys it, and I am not sure but that a good deal of the epiphora that follows splitting is the result of this. There are many patients with dacryocystitis who would not recover without extirpation of the sac. But the repeated probings that Dr. Weeks and Mr. Parsons speak of are barbarous and the repeated traumatism is damaging. The use of the Ziegler large dilator in these cases will be found useful. One dilatation gives a good opening into the duct and I have apparently cured many patients. I cannot tell how long they will remain cured, but one has been cured for a year, and several that have been subjected to the excision operation by the use of this dilator and subsequent irrigation with a 0.25 per cent. formalin solution. I have found that in cases of blepharitis and conjunctivitis and dacryocystitis the results are very good from the line of procedure that Dr. Ziegler has mapped out.

DR. S. L. ZIEGLER, Philadelphia: Complete atrophy does not occur following the stretching of the soft tissues. The tissues are so rapidly stretched that, as in any other rapid dilatation, as of the uterus, there is no contraction. I have seen a slight nick in the canaliculus itself, which soon heals and still leaves open the caliber of the punctum. As to the length of time the cures remain, I have seen recently a case in which dilatation was done eight years ago and one in which dilatation was done fifteen years ago when the child was 3 months old, with a severe dacryocystitis, practically, I presume, congenital. In the latter case dilatation was probably done more easily on account of the very soft condition of the tissues. I used the large end of the dilator as I have in every case. We see many cases of enucleation in which there is a chronic discharge from the socket. I have been able to relieve the postoperative condition by stretching the duct. Apparently there has been enough regurgitation from the nose to create this condition in the socket. That brought me many years ago to stretching in all cases of enucleation for the purpose of preventing this condition, and I certainly have had cleaner sockets in my practice since that time than previously. The bismuth paste of Beck which is being used by all surgeons in sinus work and in taking *x*-ray photographs has proved to be very satisfactory, although, as stated in the paper, I have not used it long enough to be absolutely satisfied. I have been using a cold paraffin syringe for forcing it into the duct. It is possible also to use it by dissolving it, as Beck does, and using it in the fluid condition. The illustration shows the instrument as a trifle sharper than it actually is. One end is rather sharp and I use it as a needle-probe and follow it by the large end. The needle probe is quite sharp, as all needle-probes should be for passing from the punctum to the sac. I have not seen false passage. It is possible, but I do not see how it is probable with the large dilator, as there is no room in the duct for a false passage unless we force it through the bony passage, or there is necrosis of the bone and then we should have an eye in the end of the dilator.

I explicitly stated in the beginning of the paper that I was not raising the question of extirpation, but wished to avoid it. In the cases reported extirpation was out of the question. I have recently seen a case in which, according to the patient's statement, the sac had been removed three times, and in which I had to dilate. I succeeded in getting a passage, with relief to the dacryocystitis. I cannot pass judgment on the former surgical work, as I do not know what was done, beyond the patient's statement.

THE THERAPY OF WORK*

ROBERT S. CARROLL, M.D.

ASHEVILLE, N. C.

A distinguishing characteristic of the developed human mind is its vision of unity, that power of seeing more or less clearly the whole through the part; and to our profession is peculiarly granted the large opportunity of studying man as a whole. The incompleteness and one-sidedness of much which has been called medically scientific is to be replaced by that broader grasp the whole man's needs, which has ever been the province of great physicians. This paper is written to add whatever emphasis it may to the now accepted law that man is mentally, morally and physically so attuned that when disordered, his perfect restoration demands intelligent readjustment of each element.

CLASSES OF INVALIDS

An injury may be primarily mechanical, chemical or psychic. If the original damage deranges the mechanical workings or integrity of the body, we speak of the condition as surgical, and these most obvious of all injuries have been the objects of increasing skill through the centuries of medicine, until to-day anatomic knowledge and surgical technic allow us to invade every precinct of the body. The wonderful development of this branch has, unfortunately, had its attendant evils, and but few years have elapsed since surgeons who called themselves able and honest were removing practically normal organs, and subjecting patients to exploratory incisions for the "mental effect." It is good to state that that phase of the surgeon's work has now reverted to the tyro and charlatan.

The secrets of metabolism and secretion reveal themselves all too slowly, and the modern physician, even with his years of careful, special training and his immense therapeutic armamentarium, must still feel the stigma of empiricism as he faces many of the baffling disease processes of internal medicine. Yet to many of us our patients have appeared either mechanically out of order or suffering from damaging chemical perversions, while we have ignored the very core of the sufferers' being, the psyche, that principle of life connected with, dominating, and making real the body. For years the neurologist has been pleading for a hearing in behalf of the suffering thousands on whom the surgeon has operated and reoperated, the internist toniced, depleted, stimulated and narcotized, pleading for an intelligent recognition of the fact that a certain percentage of invalids are nervously, that is, psychically sick.

THE NEUROPATH

History tells of no age which did not produce its quota of neurotic sufferers, most of them victims of perverted ideas, and few of the nervous may be found, who do not possess some moral perversion or weakness. A young wife loses her husband. The emotional shock from which she suffers is too frequently interpreted through her physical sensations. From the strong, useful woman, she rapidly becomes self-centered, her body responds to her mental suffering in the form of various perversions of sensation, and with the assistance of the physician, who has a powder for every pain, the man who has failed to apply his psychology, she starts her round of treatment, passes through the hands of the family physician, the oculist, abdominal surgeon, the osteopath, and finally finds her cure in the negations of Eddyism—and medicine is rightfully discredited.

A daughter of affluence, reared with every false protection, condemned to a life of enervating ease, and hounded by the apprehensions of a doting mother, with her reiterated suggestions of care, slips on the waxed floor of her palatial prison and injures her knee. Yes, it "looks tuberculous," and is put into a cast, later she is taken to the orthopedic specialist, is *x*-rayed, nothing is found. Months pass, and in spite of massage, Swedish movements and special nursing, she remains a cripple unable to walk. Five years later, a humble chiropractic, with his preliminary training as streetcar conductor, and a year's course at his special school of learning, lifts the head of a rib from some hypothetical, compressed nerve-plexus, and the patient walks, she dances, and the family shouts praises, but not of our profession.

She has been married six years. The only little one was taken, and as time passes, hopes for the fruition of mother love weaken. Her husband is not as thoughtful as formerly, and when he comes in late is sometimes unkind. Gradually the heaviness of her heart becomes a load on her stomach, and the doctor, who forgets this little woman's mentality, calls it indigestion. Of course, it is pepsin and the whole long list of digestants and tonics, and then the specialist uses test meals and performs lavage, and the stomach-washings and prison fare help for a while. Then the patient cannot sleep and the mental depression suggests rest cure. She returns home in good color and good flesh and everybody says she is well. But within a year she is worse than before. A great opportunity has been lost during those weeks of rest, because her mental needs have been neglected. Fortunately, financial reverses come. She must do her own work. Care of self is out of the question and a dead sister's children are brought to add their needs to her burden—needs which call out that strength so long unused, inherent and yet unrecognized by the physician who saw in the human body only a machine of mechanical construction and a laboratory of chemical reactions. These cases but inadequately illustrate the diversity of the neuropath. All of us come in contact with examples equally pertinent if we will but see.

---

* Read before the Tri-State Medical Society, Richmond, Va., February, 1910.

The neuropath may be of the hereditary type. If so, his case is usually difficult. The acquired form may result from exhaustion, intoxication, or have its birth in its owner's brain. Theoretically, the exhausted class is large; exhaustion is an extremely popular, one might say, praiseworthy disorder; and the overworked neurasthenic receives much gratifying sympathy. In fact, the case of pure exhaustion is rare, but when existing, demands the full rest-cure. The rôle of frank intoxicants, alcoholics, mineral poisons and the narcotic group, in producing nervous damage, is common knowledge. The influence of the autochthonous poisons, while long disregarded, is becoming much more generally understood, and those definite symptoms following hypothyroidism and hyperthyroidism, altered intestinal flora and defective urea elimination, now receive intelligent attention. Not enough thought is given, however, by most of us to the rôle played by the excessive ingestion of highly organized foods by those who live lives of muscular inactivity. Disproportionate calory ingestion to calory consumption is the too often undiscovered cause of nervous breakdown. But the mind's own concepts and morbid moods are sources of the large part of nerve suffering, and I must again emphasize that law of unity which impels mind and body to respond to the constructive power or damaging depression of our emotional selves.

It is a dreary list we recount, as we tell over those injurious influences which are so specific in the reduction of nerve integrity: profitless introspection, morbid self-consciousness, ultrasentitiveness, self-depreciation, cynicism, pessimism, doubt, and that influence most baneful of all, fear in its many forms: dread, apprehension, embarrassment, terror, horror, fear of sickness, fear of injury, fear of the elements, fear of scandal; and those more prolonged states including enemity, grief, sorrow for loss, rebellion of death, envy, jealousy and hatred. Are these *not* the toxins of the soul? And what has surgery and medicine to offer as antidotes? Perchance, the physician may with his belief in his diagnosis and treatment inspire the sufferer with his own confidence in the scalpel and his potions, but the unending list of failures has long proclaimed the need of a true psychotherapy. The call is universal for men practised in all the arts of medicine, and in addition students of the human mind—men who will investigate every somatic deficiency, and with equal honesty, intelligence and precision, seek out and find the psychic need. The very length of the list of false psychotherapeutic cults but emphasizes the need for a true, rational psychotherapy. Mesmerism, healing clairvoyants, and voodoo doctors, faith-healers, homeopathy with its half-truths, osteopathy and its child, the chiropractic; the barefoot cure, goat-lymph, the great cult of Eddyism and its more orthodox associate, Emmanuelism, the miracle-working prayer-cure, charms, amulets and incantations, all assert in a chorus most emphatic the fact that beliefs, though false, may displace morbid ideas and effect cures. This truth must come home to us with a reiteration that may not be denied till a rational psychotherapy becomes as definite a branch of scientific medicine as is obstetrics or surgery. What this science in its fullness is to be is yet unrevealed. Workers are multiplying and in the absence of perfected methods, each is striving with his light to approximate the ideal.

PSYCHOTHERAPY

A number of years devoted largely to the development of a workable, practical psychotherapy, have convinced me of the preponderating value of work as a present help, as well as a lasting benefit, in the treatment of the nervous, and this even in the face of the oft-reiterated claim of these patients that they are suffering from overwork. The great value of Dr. Mitchell's rest-cure is unquestioned. It will not be displaced as a form of treatment in numbers of cases. Often, however, is it unwisely used, and too frequently proves inadequate, though helpful even in cases of exhaustion. With its wise supervision of diet and the oxidation incident to ample massage, it fills the immediate need in many toxic cases, while during the weeks of isolation, physician and nurse have the rarest opportunity to employ persuasion and to substitute wholesome, rational thought life for murky and morbid moods. Unquestionably, it fills certain needs, but that great law of our being, that for which our bodies were formed and our minds endowed, directed action, is not fulfilled.

The Law of Work.—Work truly is life, and any treatment which ignores every means which will make possible such life in greater abundance, cannot be comprehensive. Stanley Hall has well said, "The human body is made for action and it has other muscles than those that wag the tongue or move the pen. Many starved longings and unrealized desires are but misinterpreted calls to work." Lotze's conclusion in comparing the human body with other animals, is that "man stands at the head of the scale of creatures when estimated by capacity for work. Some animals are swifter, some are stronger, some are longer-lived, but none have such combined advantage in capacity for work. The human body is made for action."

The Therapy of Work.—In prescribing work as a therapeutic measure, a proper form should be specified. Physical employment well within the strength of the patient, productive in nature, so that its effects may be permanent, and employing sufficient mental activity to distract attention from the purely physical, is the ideal. But even drudgery has its place. A large part of the world's work is drudgery, and to the pampered neuropath there is a wholesome discipline in working for work's sake. There comes a development of will hitherto unknown in the accomplishment of common foot tons of labor.

It is unnecessary to state the physical benefits of manual labor. No man is living his best who does not daily put into activity that large bulk of his physical body, his muscular system, and into such activity as will call for a virile expenditure of energy. A large majority of neuropathic patients have worked for years along mental lines, and even though there may have been some physical expenditure it usually has been associated with emotional wear and tear. The mental relaxation and rejuvenation which follow substitution of reasonable physical employment for high-pressure mental strain, cannot be gainsaid. While there is no question that energy may be trained to flow into either physical or intellectual channels with equal efficiency, wholesome benefits to the mind come from the physical exaltation following the normal use of our muscles. But the greatest influence, the true and lasting benefit in work as a therapeutic agent, rests in the moral uplift, the great mastering of self which comes when one is taught to work right, when one knows the joy and forgets the burden of doing, when self-mastery displaces indulgence, when doubt of one's strength and ability is replaced by faith—faith which grows out of visible evidences of one's accomplishment—when morbid self-centeredness, that miserable dwarfer of the soul, gives way to an externalizing self, the forgetting of self in its relations with people and things; then the passion for material comfort will lose its devitalizing power in the face of that independence which comes with the toughening and the strengthening of will, the off-spring of productive accomplishment. Theory, sermonizing, the stimulation of music and art, the inspiration of poetry and song, have their places in the needs of many-sided man, but for developing power and character and for making man's spirit master of his body, mortal man has to work since the days of fair Eden. In fulfilling the law of work, man's spirit may not only master itself and cure itself of its quirks and quibbles, but to a surprising degree may obtain and retain a mastery over the body, which it should normally rule, a mastery superior to petty discomforts of temperature and weather and the habits of our neighbor's children and the din of traffic, a mastery superior to the miserable hyperesthesias and dysesthesias so incident to nervousness. "Is there not a crying need for that physical education which inculcates habits of obedience, mental concentration and application, and forces into the background the former man?"

REPORTS OF CASES

From a list of happy results, based on the physical, mental and moral benefits following the insistence on physical work in broken-down neurotics, I append a few short histories:

Case 1.—Mr. E., aged 50, was reared on a farm, and developed a superb physique. At 22 he went into manufacturing; at 46 he was a millionaire, and a depressed, sleepless neurasthenic, fleshy, soft, and continually anxious concerning the uncertain health of his wife, a chronic hysteric. For two years he rested, took hydrotherapy in Europe, and sought sleep in the extremes of climate until his depression seemed to anticipate an early mental disruption. An unusually intelligent attendant, isolation from his family, one-half mile leisurely walking, increased in ten days to three miles fairly brisk walking, the prescription of a wheelbarrow and spade and so many feet of sod to move each day, with some simple problems in landscape gardening, and a later explanation of the nature and mortal innocence of his wife's hysteria, resulted in a growing confidence. The walks were increased and mountain-climbing added. At the end of three months, a two weeks' tramp, "rough and tumble" over the Black Mountains, sleeping in the open and reaching 20 miles of mountain tramping a day, proved his declaration of independence. His soft 225 had become sturdy 1[illegible]0 and he returned to his family superior to worry, sleeping and eating normally, because he was living rationally—and he has lived rationally these five years. But he writes that he has never found a substitute for the wheelbarrow and spade.

Case 2.—Miss M., at [illegible]3 was a healthy, well-nourished woman with no object in life,, and a worrying solicitous mother. A fall injured her back, her left leg became helpless,.and troubles multiplied. A ventrofixation was done; a second operation removed the appendix, a third an ovary. Nine months of one year were spent in a surgical hospital. For five years the patient was unable to walk a block unassisted. Repeated vomiting and "colitis" seemed to add, at times, a grave element to the case. A course of rest treatment failed. Varied diagnoses were made. Six weeks' isolation with strict discipline, the overcoming of fear of the stomach-tube by its daily use, convincing the stomach that it could digest, and digest well, large quantities of nutritious food, revealing to the patient her constant habit of autosuggestion, paved the way for two months rapidly increasing out-of-door work, transplanting shrubs, digging, and long mountain tramps. Progress from one hobbled block to nine spry miles—her daily average six miles—sent her home eager to take a useful place in life and to use her new-found strength productively.

Case 3.—Mr. B. inherited wealth and for fifty years was a dilettante. He played at work, he played at business. Doubt was his enemy and doubt broke him down at 28, but the diversions of a trip to Europe restored his ability to play at work. At 42 doubt again divided his energies. Europe failed, but interest in a new New Hampshire farm, with a new variety of play work succeeded. At 48 his doubts and their attendant fears rendered him incapable of signing a check, selecting a tie for the day or deciding whether to take his walk or sit by the fire. Europe was again tried; the New Hampshire farm this time proved unavailing and two years of life were wasted. Physically, the patient was in excellent shape. His trouble was his mentality. He had never had to do a real thing. Isolation was advised. In addition to a rational routine, a bushel of rusty, crooked nails was given this hereditary millionaire to straighten. There was immediate and energetic rebellion. The gentle logic of persuasion was employed to convince the sufferer that as he had found his strength inadequate to decide even the pleasures of life, the demand that he develop the will by daily performing that which was undesirable, first suggested by another, later as the will strengthened, planned by himself, that some time every day should be spent in the performance of those tasks he would prefer not doing, was the ground on which his battle must be fought. The progress was rapid. He even became zealous to straighten the whole bushel unassisted, and to-day writes in praise of crooked, rusty nails as the best chalybeate for moral anemia. He now works every day certain hours with his muscles and certain hours and efficiently, with his brain.

Case 4.—Miss L., of delicate ancestry, grew into young womanhood with no training for self-support. Misfortune reduced the family income, and her efforts to utilize her excellent education for practical ends threw her into contact with a woman of strong passions, and an intense mutual attraction followed. Under the woman's influence, the girl's sexual initiation occurred. Later she was separated from her ardent friend; shame and remorse and the feeling that she was forever unworthy rapidly produced a motor hypersensitiveness of unusual severity. A morbid shyness made her almost a recluse and her faith in humanity was sadly injured. A gynecologist located the trouble in the pelvis. The uterus was curetted and suspended, a cystic ovary removed and six months in bed prescribed. The patient left the hospital under the admonition to avoid physical exertion. The damage to the psyche had not been considered. Three miserable years of hothouse living followed. The motor sensitiveness became almost intolerable. The patient was a burden to herself and her family. Physiologic rest seemed impossible. An examination which sought and found the true injury was the beginning of her recovery. Her own conscience recognized her true need, and the placing of her wrong in its proper relation to life, the helpfulness which came from ventilating this darkened chamber of her existence, with ten weeks of isolation under the care of a nurse capable of giving the sympathy which inspires strength and resolution, then a gradual transition to walks and active work in the garden, followed by combined outdoor and indoor practical work, made her for the first time in her life a producer, and for over two years she has been independent.

Case 5.—Dr. W., at 40, was a surgeon of national reputation, slight in stature, with no generous circumferences save those of his cranium, typically neurotic. The doctor had had three years of unusual European advantages and had returned to his American practice with the irritations of the phlegmatic continental operators superadded to a natural mental hypersensitiveness. He worked hard, but he worked wrong. He worked in an atmosphere of criticism. Explosions of temper were uncontrolled; they bespoke the touch of genius. Ambition and jealousy contributed their corroding touch, and he broke down. It seemed entirely physical. For the last months of his work he ceased walking entirely, using his machine for even the shortest trips, depending on the elevator, and ready to abuse all things mundane which did not respond to his command. Walking became impossible. "Colitis" supervened, physical exertion adduced great discomfort in the legs and abdomen, and diarrhea was the penalty of any extra work. He was well treated physically at home and abroad, but the last state was worse than the first. It finally occurred to his physician that a neurologist might throw some light on the case. The neurologist sent him to an institution which he entered with little hope. The patient was too weak for much work. His mind, however, was very active; he was skilful with the knife and occupied himself whittling ingenious toys for his children, deriving much pleasure in applying the simpler laws of mechanics to and artistically finishing his handiwork. As this man's breakdown had not resulted from work, but from emotional damage due to his wrong moral attitude, and as no physical lesion was discernible, it was possible to ignore the physical and let him know that it was ignored. Discussion of his bodily ills was tabooed, and he and his nurse began measuring the distances from the institution to various points of interest. At the end of two months he was making five miles of good mountain tramping a day in winter weather. Three months from his entrance he was cutting loose from the trails and going straight over some of the highest of our Appalachian Mountains. Two weeks later he resumed his practice. He now operates four and half days a week, rests one day, and works in the open with axe and pick one and a half days. No day passes that he does not do homage to his muscles, and he has displaced the jealousies and vaulting ambitions and lack of self-control with wholesome motives.

CONCLUSION

Who of us but recall cases in which our best efforts have proved unavailing, yet in which the patients have recovered in response to methods which we know were crude, unscientific and inadequate? Some form of psychotherapy had remedied a disturbance of psychic source. And what more perfect influence can there be than that which recognizes the need of the whole man, which utilizes his entire capacity, which harmonizes the warring elements of his being, and restores unity, wholeness and productiveness? Such will ever be the mission of work when divorced from damaging moods.

THE DIAGNOSIS OF RETROPERITONEAL ENLARGEMENTS*

W. H. ALLPORT, M.D.
CHICAGO

I. THE METHOD OF DIAGNOSIS

This is an old subject, and yet an important thought brings perennial refreshment to its discussion, and attaches to it a more than passing value; for on the correct solution of many of these examples in abdominal algebra is based the wisdom of the choice of a transperitoneal or retroperitoneal operation.

Although I intend to deal with objective enlargement as the point of departure for my discussion, so important is everything which concerns the definite location and identity of disease on one or the other surface of the peritoneum, that I may take the liberty to digress at certain points a little, to consider cases in which the absence rather than the presence of enlargement adds confusion to the situation.

The busy surgeon has to answer such questions out of hand, without consideration of statistics or text-book classification, and reads the riddle—if at all—by the light of experience, and by the extemporaneous application of a cultivated logical faculty. We may be justified in thinking, therefore, that even when made the text of more ambitious discourses, this subject, when treated clinically, will thus yield the more lively interest, and will carry farther into the mind of the practitioner accustomed to every-day occurrences.

This paper, then, is an informal one, based altogether on a few salient personal experiences, with scant reference to authors or authorities. We can find enough of the clinically unusual in the simple recital of observations along a great surgical frontier to satisfy the most ardent seekers after diagnostic excitement.

In my student days, it was a favorite observation of an old friend and teacher—who still holds toward many of us the same beloved dual relation—that no two cases of typhoid are alike, and that no one case is ever just like the type the physician carries in his mind's eye. Just so do we find most retroperitoneal conditions; as soon as we have our ideas well formulated from a melancholy contemplation of past failures, up crops some wretched novelty in a false face to upset our notions of the fundamentals. If we start, then, with too many formulas, we shall not only cloud that clearer vision which knows a few truths and knows them well, but we can hardly reach any very comprehensive basis of diagnosis. The occasional exception may prove a rule, but too many either of rules or exceptions hamper decisive movement.

And first let us consider briefly the personal element underlying all diagnosis. A retrospect of my own many and constantly recurring diagnostic errors shows that they have been made largely either through ignoring or incorrectly valuing easily accessible diagnostic data, or else through accepting the crude opinions of others on vital points. In history-taking the statement of an absolutely ignorant patient, who is seeking relief and not damages, and who has a mind altogether virgin of opinions, is of more value than that of an educated crank with a fixed idea. In history-taking one should seek facts, and best of all objective facts; one should shun opinions—even those of colleagues. Many of the errors here frankly enumerated were due to disregard of these oft-repeated medical platitudes.

Secondly; when it comes to guessing—and who does not indulge in surgical guessing?—we should even then in the same way reserve to ourselves the right to guess independently. But we should guess as does the insurance actuary—scientifically, with the tables spread out before us. If the doctrine of probabilities, fortified in this manner, is a reasonable basis for the most conservative business in the world, why should the surgeon ignore it? To look for cancers in the old and sarcomas in the young, for acute abscess and the results of neglected trauma during the years of productive activity, and for chronic abscess and tuberculosis at all times—this in brief is the working theory of probabilities as applied to surgical diagnosis; the exceptions are few, and whoever accepts the doctrine to its fullest will be right the greatest number of times.

In this connection, let us note that many men have too much exceptional but undisciplined knowledge, and ignore safe guides for the conduct of everyday surgical life. Book knowledge brings as close familiarity with the unusual as with the usual, but leads to a disregard of averages. The commonplace man who makes a judicious canvass of symptoms and settles down behind the doctrine of averages is apt to be right the greatest number of times. The usual is more likely to occur than the unusual, and the skilled diagnostician takes this into account.

---

* Read before the Tennessee State Medical Association, Memphis, April 13, 1910.

Case 1.—*In a recent case brought into the hospital for diagnosis,* this doctrine strongly influenced the diagnosis, although the case was held to be inoperable and surgical confirmation was thought unnecessary. A rosy and well-nourished child of 4, without history of previous diseases, presented an abdominal tumor of about six months' standing. Although the patient was said to have had previous high fever, during one week's observation, there was no fever or leucocytosis, and a von Pirquet test was negative. The skiagraph was negative. There was no vomiting, constipation, or diarrhea, no pain, and no urinary finding. The bladder, however, was thick and large, and there was continual urinary incontinence. There was no axillary, cervical or inguinal glandular enlargement. The abdomen was swollen and careful percussion showed it to contain a small quantity of fluid. Behind the descending and transverse colon was a growth, extending from the extreme left flank to the outer margin of the right rectus; there was some doubt whether the smaller portion to the right of the median line was actually joined to the larger portion to the left. The left border of the growth was rounded and smooth, and could be traced well under the costal arch above, and to an ill-defined point behind the sigmoid below. There was no fluctuation, and no pain or tenderness. Within the abdomen could be felt a few less-defined lumps which were not freely movable and seemed to be more closely associated with the posterior layer of the peritoneum than with anything actually within the cavity.

A diagnosis of tabes mesenterica had been made prior to admission.

The probabilities and known facts in this case pointed toward renal sarcoma, with only a remote possibility of tabes, and it was a little difficult to see why the latter diagnosis could have been previously entertained. While tabes sometimes exists in well-nourished children, without fever, without bowel symptoms, without adenopathy in other lymphatic regions, and possibly also as a primary large rounded tumor which might even so completely encroach on the kidney region as to simulate a renal tumor, it would have to be conceded that a wide margin of probability lay against such a large and characteristically located infantile growth proving to be anything other than renal sarcoma. Nor with the secondary enlargements present would it have been possible to entertain the diagnosis of urinary cyst. The safest diagnosis, therefore, was renal sarcoma.

Case 2.—A baby, 6 weeks old, weighing but five pounds, and nourished by bottle, vomited continually. My simple mind grasped only the connection between bottle and vomiting, and I hunted up a wet-nurse. The mother, a hysterical and unreasonable woman, became alarmed and made me bring in, coincidently with the wet-nurse, a consultant. My consultant happened to be a widely read man, but somewhat mentally astigmatic; and his recent reading happening to have been along the line of congenital pyloric stenosis, he immediately saw good reason for suspecting it in this infant, and strongly hinted at an operation. This was too much for the mother; she sought shelter in the bosom of homeopathy, taking the precaution, however, to take her wet-nurse with her, and the baby recovered forthwith.

Case 3.—A supposed hour-glass contraction of the stomach was introduced into a clinic, held for the benefit of a distinguished English abdominal surgeon, and, after preliminary demonstration by an internist, was operated on only to disclose a stomach free from deformity or other conditions demanding operative interference.

Both Patients 2 and 3 presented a number of symptoms of stenosis, but also of other and simpler conditions, and a proper recognition of the probabilities should have placed them in some other category—at least temporarily.

Thirdly, it is a fair question to ask, in certain puzzling situations, What may a man be reasonably supposed to know and not to know? Even the luminous mind of Herbert Spencer reached its limitations; sadly enough, it is true, but at the end of his years he frankly admitted that he could see only a small segment of life, and even that as through a glass, darkly. Why should not we admit the same limitations? Such confession of the boundaries of knowledge is not only scientific, but appeals to the practical common sense of most patients.

Case 4.—A large middle-aged traveling man presented himself with a slowly growing tumor, not very hard, but also not fluctuating, the size of a grape-fruit, at the level of the navel and lateral to a line dropped from the right nipple. The patient had lost flesh, had slight subacute temperatures; was pale and cachectic, but not jaundiced; had no colic, vomiting, or constipation, and but slight local tenderness. The findings in urine and feces were negative. The tumor followed moderately the movements of the diaphragm, was closely associated with but under the colon, and could not be disassociated from the liver. The diagnosis was any man's, for there could be no positive answers to either of those two crucial anatomic and pathologic questions which must be answered in every case if there is to be any true diagnosis: What organ is involved? What process involves it? Incision down to the tumor at its most superficial point disclosed a retroperitoneal mass, composed of layers of fibrin and inflammatory deposit surrounding a core of old semisolid blood, which had descended from the pleura under the ligamentum arcuatum externum, and had burrowed its way along the fascial planes in front of the kidney up into the mesocolon. Closer questioning and examination during the patient's convalescence brought out a fractured rib—the result of a forgotten fall across a chair-back several months previously. It should be noted especially that the tumor could neither be associated with nor disassociated from any of the important organs lying in its vicinity. The key to the situation was ignored in the history-making.

And yet we have no right to put into any of these common ports of refuge of the indolent man until the real and available sources of knowledge are exhausted. We may rely as much as we please on common sense, and surgical instinct, and the doctrine of probabilities—these when legitimately used are merely methods of applying experience to concrete problems, and involve no occult powers peculiar to people of genius. We may in a pinch even, as in the instances just cited, shelter ourselves behind the limitations of knowledge. But none of these processes improperly employed can excuse the failure systematically to seek out, classify, and weigh all available diagnostic data.

At the bottom then, of diagnosis lies educated method, whether consciously or instinctively directed.[1]

II. THE PROBLEMS OF THE REGION

After this rough sketch of the scanty framework on which all diagnosis must be erected, let us consider a few of the special problems and diagnostic resources of this great borderland region.

There is no more promising approach to a comprehensive grasp of retroperitoneal diagnosis than one which takes normal position as a *fixed point,* but which traces, with the aid of an imaginative faculty bred of experience, the variations from that standard usually and primarily produced by perverted function. Thus we find ourselves recurring constantly and inevitably to our first years' studies in anatomy and physiology. And more so in these regions than in the extremities, for there we have a standard ready at hand in the companion limb to jog our flagging memories; whilst here, observation, memory and imagination—joint attributes of great intellects—must supply the deficiency.

---

[1] In a recent address, President Hadley of Yale made the far-reaching observation that education, by the study of abstract and often intrinsically useless subjects, teaches the methods by which the fully developed man solves the practical problems which come to him in his years of productive activity.

Many of us can recollect an instance of the operation of this great imaginative faculty, which sees the link joining the normal with the abnormal, in a memorable controversy of half a generation ago between a teacher of anatomy, and the greatest of all American surgical pathologists. The point in dispute was the relation of the structures passing to the liver in front of the *foramen* of Winslow between the two layers of the hepaticoduodenal ligament. The surgical contention was that the portal vein encroached on and menaced the approach to the common bile-duct. The anatomist scouted the idea and produced text-books and finally a pocket-edition cadaver with which to overwhelm anatomic doubts. The great pathologist—the discoverer of the ball-valve production of intermittent jaundice by stone in the common bile-duct[2]—listened silently to the demonstration, then responded: "Very good, very good, but I speak as a surgeon and a pathologist, and my relations are not yours." Those who operate on the diseased and obstructed common duct have had occasion to confirm the literal correctness of his observation.

The old arbitrary division of the abdomen by lines into geometrical regions is still the best, and no modern classification can surpass it in its clinical value. To each region anatomy assigns its own peculiar organ, and the clinician is justified in insisting that any organ suspected of having escaped from its own territory must have its identity proved beyond doubt. We can never forget that the enlargement found in the left hypochondrium should—anatomically—be spleen or kidney; an epigastric tumor should be stomach or pancreas, unless it may be a cyst of the lesser omentum; a hypogastric growth should be vesical or genital; inguinal tumors should be hernial or ovarian, cecal or sigmoidal; those in the umbilical region should be aneurismal, intestinal, mesenteric or omental; and lumbar enlargements should be renal, colonic or appendiceal. Nor should we forget that each organ is entitled physiologically to its own normal range of motion. On this anatomic basis we are justified in opening our investigation.

But right away we make two discoveries:

First: These regions are of concern mostly to the anatomist—it is the dividing lines between them, and the encroachments on them which interest the surgical pathologist.

Second: There are certain abdominal foci which represent centers of normal activity and which occur quite without relation to any arbitrary lines or divisions. These foci are apt to serve also as storm-centers from which radiate morbid processes. Such centers are points where the different physiologic systems come into contact, and here pathology also centers and the diagnostic trouble begins.

Consider, for example, the classical McBurney's point: within a circle two inches in diameter we may find normally the inflamed appendix, the cecum, and the calculous ureter; but we may also find the abnormally high ovary, the low gall-bladder, not to mention the cold abscess, the dislocated kidney, and any wandering neoplasm which claims squatter rights.

We draw another circle of the same diameter and center it at the foramen of Winslow, midway on the oblique line from the navel to the costal arch. Here are normally, gall-bladder, common duct, pylorus, pancreas, duodenum—each capable, with its train of morbid phenomena, of rapidly deranging the functions of every other organ in the vicinity.

Within the first region the displaced ovary is dragged up and plasters itself to the inflamed appendix; the ureteral stone impounded at the pelvic brim draws cecum or appendix into its troubles; the low and obstructed gall-bladder apes the dislocated kidney or the distended appendix, and the inflamed omentum covers all. It is even on record that this region has been invaded by a pyloric cancer[3] developing in a badly prolapsed stomach. In the second region, the swollen membranes around the foramen of Winslow may mask the perforated gall-bladder, the obstructed common duct, the pyloric or pancreatic cancer, or the thickened gastric or duodenal ulcer. Every surgeon of ordinary experience has faced problems which have to find solution along these lines.

Here are several examples from these regions where the important question was, peritoneal or retroperitoneal?

CASE 5.—*A fat woman, not jaundiced, presented herself with a roundish, movable tumor in the right lumbar region, lateral to and not covered by the colon. There was local pain, but otherwise no physiologic derangement. There was good basis for suspecting either the kidney or gall-bladder—which was it? Inflation of the colon by Ziemssen's method failed to separate the tumor from the loin, or to show that it belonged in the hypochondriac region. Manipulation, however, pushed it most readily forward and upward—it would not slip into the normal kidney position, and was, therefore, recognized as gall-bladder. Incision made cautiously directly down to the tumor proved the diagnosis to be correct.*

CASE 6.—*A young man entered the hospital with a round, finger-sized and shaped, painful swelling under the colon in the right lumbar region, well above McBurney's point. Several mild previous attacks, and like this one, without fever. No vomiting, no constipation. Leucocytes, 20,000; polymorphs, 84 per cent. Loin colic, but only moderately rigid rectus. Urine contained some pus. Was it the ureter or the appendix?*

Diagnosis was reasonably clear, for the tumor was too far to the right to be the ureter—which is rarely displaced. Incision directly over the tumor disclosed a very high appendix lying lateral to the colon.

CASE 7.—*A fat saloon-keeper came, after a previous operation for appendicitis, complaining that his pain was just the same. He was so fat that it was not possible to make out a tumor, but there was great pain on deep pressure in the loin. His urine was loaded with pus, and he had a constant evening temperature of 101. The enlarged kidney pelvis was incised and drained, but the temperature continuing for two weeks, it was found necessary to remove the kidney. After separating all of the organ except the upper portion, I finally tore that loose from some dense adhesions, and with it tore out the lower wall of a great subphrenic abscess, the existence of which had never been suspected. The patient had a good left kidney and recovered perfectly in spite of repeated blunders in surgical diagnosis.*

Now strangely enough, the spleen also frequently becomes the center of unjust suspicions. One would suppose theoretically that an organ so definitely located and so securely placed would hardly mix matters very seriously for any of its neighbors. It should be traceable, if enlarged or prolapsed, back into its pocket under the deeply concave roof of the diaphragm, and if it pushes downward it should also project forward and lie superficial to and cephalad to the colon, which falls with it. And yet my note-book recalls two cases in which although we held a strong belief that the spleen could not be excluded, the culprit proved to be another organ.

---

[3] Osler: Lectures on Abdominal Tumors, New York Med. Jour., Feb. 3, 1894, p. 132.

CASE 8.—A Montenegrin who spoke no English entered the hospital for treatment. His previous history was negative of all facts which could throw light on his present condition. In addition, the temperature, weight, blood and urinary findings were negative. In the left side, projecting from beneath the ribs, was a roundish solid tumor in which one could feel a notch not unlike that of the spleen. The tumor moved with respiration into the abdomen, but could best be felt in the flank. When the colon was inflated, the tumor was still found to lie more in the flank than toward the median line, but the colon was displaced downward. I erred in giving this latter point too great weight—the tumor was a large hypernephroma, pushing the spleen up and the colon down. The respiratory mobility was transmitted to the tumor through the spleen. The key to the diagnosis was the great lateral growth into the loin under the peritoneum, instead of toward the navel within that membrane.

In a second case, the spleen was called on to prove an alibi in another direction.

CASE 9.—A parchment-colored and emaciated native from the American Nile district around Cairo wandered up to Chicago with a tumor. The growth was larger than an Osage orange, and projected from beneath the left costal arch into the epigastric, umbilic, and left lumbar regions, but in a plane not usually invaded by the spleen. It could hardly be called movable, and its lower border was none too well defined. The tumor and the patient's history and residence suggested a malarial spleen; but although the red blood cells were reduced and irregular, there were no parasites, and persistent vomiting pointed strongly to the stomach. An analysis of the stomach contents after a test breakfast showed no blood, but hydrochloric was replaced by lactic acid. On this analysis a diagnosis of probable cancer of the stomach was based, but I held that the spleen could not be excluded. An incision showed a cancer of the distal extremity of the pancreas with secondary involvement of the greater curvature of the stomach. The spleen was normal.

Instances of situations in which organs encroach on and must be differentiated from one another might thus be multiplied until the limits of this paper were reached. But enough has been said to develop certain added diagnostic truths with which to supplement the division of the abdomen into anatomic regions, physiologic centers, and pathologic boundary lines. The following simple generalizations will be found to harmonize with scientific views of the influence which normal anatomy has on the development of abdominal disease:

1. The zones surrounding the different physiologic foci just enumerated are well defined under normal conditions, but overlapping often occurs when the range of motion or of growth of the organs lying within them becomes pathologic. This occurrence alone is strong presumptive evidence of disease.

2. In studying those cases in which change of position is a factor, two important aids to diagnosis are noted:

A. Displaced organs—"unknown quantities"—when manipulated, still show their easiest range of motion toward, rather than away from, their normal centers.

B. In cases in which an organ enlarges abnormally its direction of growth is still within the zone and cleavage plane normal to that organ, and rarely into or across new fascial planes. This last generalization is subject to apparent exceptions in cases in which large growths push the planes ahead of them, in which malignant growths involve all planes, and in which an intraperitoneal growth takes on a pedicle. It finds its most brilliant application in the diagnosis of those chronic fluid accumulations which occur so frequently in the retroperitoneal spaces.

III. COLD ABSCESS

There is another important factor which I have separated somewhat from our study of organic diagnosis, because it has to do pathologically and clinically with a process rather than with an organ. I refer to that greatest and most confusing of all elements which cloud abdominal diagnosis—the cold abscess.

If one were looking for a universal point of departure for a system of differential diagnosis, one need go no farther than the study of the many-sided aspects of chronic suppurations. This phase of the subject cannot be studied too much, nor can we see and remember too many of these cases, to keep us alive sufficiently to the fact that we have them always with us, and always under fresh disguise.

Let us analyze briefly some of the essential features of these pseudo-growths and pseudo-organs—for such they invariably appear to the clinician as they occur in the retroperitoneal space—in the hope that out of their apparent and invariable irregularity we may develop some sort of system.

1. They involve spaces and fasciæ, rather than organs, and when organs are involved in consequence of the anatomic arrangement of fasciæ, these are merely imbedded in the abscess and are not a part of it.

2. Through the insinuating properties of the liquids of which these accumulations are composed, they follow the fascial planes more definitely than do either tumors or organs, and are apt to assume elongated and unusual shapes.

3. But on account of their hard rind of fibrin and inflammatory tissue, as well as of the tense fascia which surrounds them, they rarely fluctuate and easily simulate roughly the adjacent solid organs or tumors.

4. But this similarity is apparent rather than real. The growth is atypical and the simulation if closely pressed does not conform to type in vital particulars. Organic diagnosis, whether of the normal or of the diseased organ, finds itself—as the French say—in an *impasse*, and this very fact should lead us to suspect the donkey in the lion's skin. In this phase of diagnosis, we should be ever on the alert to entertain suspicion, even if organic exclusion cannot be positively established. If "probability is the rule of life," we cannot escape here the doctrine of probabilities, for there is no patient too young or too old to be immune to infection, and chronic abscess is more common than any other pathological process.

5. More than elsewhere, do we find these cases clarified by a study of the history. In one of the cases (Case 3) already cited, the discovery of the half-forgotten traumatism to the chest would have thrown a flood of light on the atypical quiet tumor in the right lumbar region.

CASE 10.—In another case I was fortunate enough, through a study of the history, to identify an enlargement low down in the left lumbar region, as a pulmonary abscess which had burrowed from the lung beneath the diaphragm and lumbar fascia. This patient was supposed to be dying of consumption. Temperature was hectic; expectoration was profuse, but without tubercle bacilli. The history showed that her trouble began with pneumonia, and physical examination showed the left lower lobe well broken down, with the rest of the lung in fairly healthy condition. The tumor did not fluctuate, but the inference was plain that the cause lay eight inches away in the lung.

Less obvious are those insidious cases in which the abscess drifts down from some forgotten trauma to the spine, or from traumatic hemorrhage so near the kidney or colon that quiet infection takes place after the lapse of weeks. Such cases are especially obscure when the elevated temperature is only subacute and the white count but 9,000 to 11,000.

CASE 11.—In one case the abscess pointed at the base of Scarpa's triangle and was taken for an iliofemoral aneurism on account of transmitted pulsation.

CASE 12.—In another, there was a history of a bad fall with subsequent inability to work on account of great pain throughout the pelvic and lumbar regions. Subsequently a painful hard, irreducible tumor appeared in the groin, which many surgeons identified—for no particular or obvious reason—as a "traumatic hernia." Incision proved it to be a psoas abscess, and a skiagraph demonstrated a carious spot in the lumbar spine.

In these two cases the error in diagnosis was hardly excusable, for a reasonable inquiry into the history, and a more careful investigation into the local findings would easily have shown that the conditions suspected in each case were clearly impossible. In the first case the most casual application of our ordinary knowledge of the stigmata of aneurism would have effectually blocked that diagnosis—the pulsation was not intrinsic but transmitted; there was no bruit. The same method should have saved Case 12, in its travels from surgeon to surgeon, from an impossible diagnosis—an incarcerated and irreducible hernia could not have existed for twenty-four hours without the most fulminant abdominal symptoms; this patient had a soft painless abdomen and normal bowel movements.

In another case, however, no such charge could lie, for several surgeons worked long and intelligently for a diagnosis before the operation disclosed the true nature of the disease. This case is cited in detail in order to direct attention also to a practical application of a new and very important aid to diagnosis by exclusion:

CASE 13.—E. M., a baker, aged 47, entered the Alexian Brothers' Hospital to be treated for chronic neuralgia and sciatica. He made his own diagnosis and was assigned to the medical service. He complained also of chronic asthma, due to the inhalation of flour in his trade. The lung findings were negative; and the evening temperature was persistently normal, with a pulse of 60. The urine was normal; the blood was slightly deficient in red cells, and the white cells were 6,300. The sciatica was left-sided, and there was also pain along the anterior crural nerve. Treatment was antirheumatic. After several days an irregular tumor was discovered in the left abdomen which was described by the history-writer as kidney-shaped, but which was, on more careful examination, found to consist of two somewhat distinct masses—a small one beneath the costal arch joined to a large one near the sigmoid. Inflation of the colon showed the tumor or tumors to lie behind that structure, and covered by it, except where the size of the growth caused it to project into the flank. The growth was hard, non-fluctuant, and fairly movable, but only the upper mass moved with the diaphragm. By the medical officer, the tumors were thought to be primary and secondary sarcoma of the kidney, and the patient was referred to the genitourinary service.

Repeated examinations of the urine drawn by ureteral catheters from the separate kidneys gave only normal findings. A lead probe was, therefore, introduced into the pelvis of the left kidney through the ureter, by Dr. H. L. Kretschmer under the direction of, and by the method described by Dr. L. E. Schmidt.[4]

The patient was then skiagraphed with probe *in situ*. The plates showed no stone and no tumor shadow, but the ureter was shown to be displaced toward the spine and the probe passed well beyond the tumor region, thus excluding both kidney and spleen.

On these findings, the patient was transferred to the general surgical service with a probable diagnosis of cancer of the bowel developing into the mesentery.[5] In this diagnosis I could hardly concur, for there were no bowel symptoms such as should have been caused by so large a growth—distention, obstruction, mucous or bloody stools. Inasmuch as there was no spinal pain or deformity, I still suspected a new growth near but not connected with the lower pole of the kidney and not involving the ureter. The age of the patient made sarcoma more possible than probable, and a suspicion of fluctuation recorded prior to operation made it not impossible that we were dealing with a cyst from the lower pole of the kidney.

It was at this point that the doctrine of averages should have found recognition, for what more natural than to remember that a swelling, painless and irregular, possibly fluctuating, and incapable of certain association with any organ, should be a cold abscess? On the other hand, the absence of fever, the painless, normal spine, the advancing age, the failure to elicit a history of trauma, all pointed away from that conclusion.

There was nothing in this case to give positive support to the diagnosis of abscess except the doctrine of averages, and the great surgical truth that malignant disease is usually of organs, while chronic abscess involves fascial planes and spaces, with all the irregularity of form, development, and location which fascial anatomy implies. And yet the tumor proved to be an ordinary cold abscess, and subsequent skiagraphy showed it to have originated from a quiet carious process in the body of the second lumbar vertebra.

IV. PAIN AND HYSTERIA

It would be a grave omission if I failed to mention—even in this superficial enumeration of the more puzzling clinical aspects of retroperitoneal diagnosis—the parts played by pain and its great twin motive, hysteria. I do not here refer to patients in whom there is obvious tumor or obvious variation from physiologic standards—such patients can be safely studied along objective lines. But there are many cases through which, to the surgeon, pain moves like a minor and elusive discord, and he can neither silence it nor seize it because the key in which it is pitched is altogether subjective. Yet to the patient, pain is no secondary overtone, for in the absence of its vibrations many a tumor has reached a hopeless size even before diagnosis has been sought, and many another pathologic deposit thus solely announces its presence subjectively long before mere volume—its "fundamental"—makes it known to the surgeon. Such cases present psychologic phases which call out the real genius of the diagnostician, and no child either in surgery or worldly wisdom can solve them. For oftentimes—in patients suspected of hysteria—they demand an analysis of occult motive, and a weighing of the genuineness of pain, which would do credit to a prosecuting attorney.

Now, whatever may be said about "the curative effects of operations *per se*" in hysterical patients—and we should not be slow to acknowledge that for the hysterical patient, who can be positively identified as such, there is nothing so much deserved and so calming to the troubled soul as cold steel—the surgeon, at least, for the honor of his craft, should understand and should record beforehand on his operating book, his diagnosis and the object of his incision.

It is a grave question whether pain which the surgeon believes to be genuine, but which exists alone and as the solitary symptom, can ever justify him in cutting either into the peritoneum or into the retroperitoneal space. My own experiences in thus venturing for exploration into these great dark labyrinths, with no other guide than the expressions of pain, have been sad indeed.

CASE 14.—An old friend, a very stout florid woman at the menopause, came to me complaining of pain in the left iliac region, and of continued hemorrhage from the bowel. I found no hemorrhoids and no cause for the bleeding. She took purgatives constantly, complaining of obstinate constipation; she had a good appetite and was losing no flesh. She took a very gloomy view of her case and wished an operation. I refused, and sent her to a colleague for an opinion; he thought her symptoms suspicious. On account of her size I still hesitated, but under pressure consented to use the sigmoidoscope and to remove a few tags of hemorrhoids. The sigmoidoscope showed nothing, but she presently returned and urged a laparotomy. This was performed and the sigmoid and iliac regions were thoroughly explored in spite of enormous deposits of fat. Nothing was found, and the patient died on the seventh day of ileus. Her sister had died a few months before of cancer.

---

[4] Kolischer, G., and Schmidt, L. E.: New Method of Skiagraphic Diagnosis for Renal and Ureteral Surgery, Nov. 9, 1901, p. 1228.

[5] A very similar case is cited by Osler: Lectures on Abdominal Tumors, New York Med. Jour., May 5, 1894, p. 545.

Case 15.—"*Aus meiner Docentenzeit*"—not my case. A nervous young school teacher complained of pain in the right loin radiating into the penis and testicles, with frequent and painful micturition—as often as every twenty minutes; the urine was strongly acid, but otherwise negative. This patient cheerfully went through four operations—the last a nephrectomy—and died after the last through the slipping of a ligature placed on the renal artery. Absolutely no anatomic basis for the pain was found at the post-mortem.

In these two cases, literal acceptance of the patient's statements led straight to the operating-table and the dead-house—and yet, in the light of the result, we can see that there was not a single symptom, either objective or subjective, which did not pass through and receive improper and exaggerated color from a panicky patient. It is a fair question to ask whether the patient or the surgeon was most the victim of hysteria.

There is, however, a certain morbid yet legitimate delight which probably every surgeon has felt in allowing plainly hysterical patients to reach the operating-table, simply by permitting their vicious and lying symptomatology to work itself out to a logical conclusion. We may fairly ask, why not take such patients at their word, and let them suffer the consequences? But always with our eyes open.

Cases 16 and 17.—Two hysterical patients complaining of pain in the left kidney were operated on without other symptoms and without operative findings. One, a fat old person with chronic hospitalism, was operated on by the loin route, and the kidney fastened—no result; she lived, of course. In the other—long known to the operator as a hysterical offender—a median incision was made; a nephroptosis was present on both sides, but inasmuch as pain was present only on the left side, the kidneys were not touched. A retroverted uterus was treated by the Alexander-Adams method. This patient became pregnant presently, and forgot her loin pains in more genuine twinges when the round ligaments began to tighten up.

In this connection we should not fail to note the close association so frequently observed between hysteria and the various forms of visceroptosis. It is hardly safe, however, to attribute the morbid mental state to the ptosis—more probably the two derivatives lead back to common roots in malnutrition and venous stasis in all the body cavities.

In my experience, operations have no terrors for the hysterical, and there is nothing gained by trying to scare such a patient out of her pain—in fact the mere hint of an operation is often seized on as a source of renewed excitement and the victim takes positive pleasure in mounting the operating-table.

On the other hand the mere existence of unidentified pain and the willingness of the patient to undergo repeated operations are no positive evidence of hysteria. To the student who combines the study of human nature with that of surgery the following case will have a deeper significance than when studied merely as a problem in diagnosis:

Case 18.—A hardworking, good-looking Irish woman of 35 was employed in the millinery department of a large store. Her occupation justified a certain amount of hysteria, but she was possessed of unusual intelligence and poise. Her interesting and suggestive history was as follows:

About a year previously she had begun to have pains high up in the rectum, with rectal and vesical tenesmus and occasional incontinence. Her menstruation was more than usually painful and she had pains in the thighs and in one great toe, alternating with numbness, and acute cramps in the same calf. There was also a constant and oppressive deep pain in the back in the sacral region. During the year she had been operated on twice—the rectum, cervix and urethra had been thoroughly stretched, and the rectal mucosa had been trimmed clean of various supposedly offending polypi. Still the pain, etc., continued. My net finding was a retroverted and adherent uterus, with a suspicion of a large right ovary adherent high up. Abdominal palpation showed nothing. Median laparotomy was frankly exploratory. The theory was the usual one of retroversion, sacral adhesions, hard work, referred pains, with a liberal allowance of easily accounted-for hysteria. After freeing adhesions and raising the uterus, the finger sweeping over the rear pelvic wall detected, beneath the peritoneum and quite out of sight, a hard tumor the size and shape of a half plum and growing from the sacroiliac cartilage. The tumor was admirably placed to elude detection by either abdominal or rectovaginal palpation, and but for the instinctive and final exploratory sweep of the finger would probably have remained undiscovered, until the slow growth of ensuing years would have brought it within palpating distance. The tumor was a metastatic deposit from a hypernephroma. (Report of Dr. LeCount.)

Such a case gives us pause in the too free use of those diagnostic refuges—"hysteria" and "referred pain."

V. CONCLUSIONS

To sum up these very fragmentary observations, let us formulate a few conclusions, bred of that sober second thought which comes from the contemplation of personal catastrophe.

Method—educated method—lies at the bottom of all diagnosis. The genius for surgical diagnosis is rarely anything more than systematized knowledge.

The surgeon should take no man's word in abdominal diagnosis—he should do his own guessing, but do it scientifically.

He should recollect that abdominal diagnosis, like all applied knowledge, has its limitations—it is more scientific to announce that they have been reached, than to confess error later on.

"Probability is the rule of life," and the rule holds equally good between the ribs and the pelvis.

Abdominal regions are for the student of normal anatomy; boundaries concern the surgeon and the pathologist.

Displaced organs still move most readily toward their normal habitat.

The growth of the abnormally enlarging organ is still apt to occur within the zone and fascial plane normal to that organ; such growth is usually along, rather than across the normal cleavage planes; to the surgical pathologist the part of anatomy which is most profitably studied is that which concerns the distribution of fasciæ.

Neoplasms are usually closely associated with organs; the irregular and atypical enlargements which follow fascias rather than organs are apt to be either secondary deposits or chronic suppuration—more likely the latter.

In case of doubt, one should never forget that archdeceiver, the cold abscess.

Chronic suppuration is rarely recognized by the direct method—the rule is diagnosis by exclusion.

Attention is especially directed to the history sheet, the temperature chart, the blood-count and the urinalysis report.

Inflation of the colon by Ziemssen's method often enables us to assist diagnosis by crowding the tumor into one or the other space in front of or behind the posterior layer of the peritoneum. If the growth is found by this method to be retroperitoneal, the kidney should be studied again by palpation, urine analysis, the *x*-ray, and finally by metallic ureteral catheterism combined with skiagraphy.

The neglect to recognize and properly to appraise hysteria is as frequently a cause of the miscarriage of diagnosis as is the failure to identify the cold abscess.

During those impressionable years which succeed every man's graduation from college, I served in a large hospital and followed many cases from the medical to the surgical wards and often—it must be confessed—to the dead-house. It was our privilege—which even then we recognized to be a glorious one—to serve under a man who thought little of time or money and much of the honest foundations of his great art in diagnosis and pathology—Christian Fenger. He made mistakes, but under the inspiration of his method they were to our fecund minds more vitalizing than the triumphs of other men. For from his own errors, he taught himself and us, and led the way to a keener search for future truth. "Did we observe all the observable facts?" "Were the facts distorted by passage through refractory media or by incorrect methods of observation?" "Well, then, our deductions were wrong, and we must observe and reason better next time!"

607 Rush Street.

INTESTINAL OBSTRUCTION FROM ASCARIDES LUMBRICOIDES

REPORT OF A CASE

RICHARD E. VENNING, M.D.
CHARLESTOWN, W. VA.

The older authors denied the possibility of obstruction from this cause. Treves, in his work on obstruction of the intestines, expresses the opinion that "there is no trustworthy illustration of this somewhat rare form of intestinal obstruction."

Peyrot[1] does not mention a single case in his exhaustive observations on intestinal obstructions.

Rilliet and Barthez[2] think it possible, but state that strangulation caused by worms must be exceedingly rare.

D'Espine and Picot[3] contend that not a single example of intestinal strangulation exists, at least in the case of a child.

Galvagno Bordoroni in 1887 was the first to report a case of obstruction from lumbricoides, which he confirmed by the post-mortem examination. In the same year Stepp[4] speaks of a case of a 4-year-old child in which the post-mortem showed fifty ascarides, hermetically sealing the lumen of the bowel.

Taylor[5] in 1899 reported a case in which he operated and found two feet of the ileum inflamed and edematous. He opened the intestines and delivered sixty-six worms in a mass producing the obstruction. The intestine was damaged beyond repair and the child died on the third day after the operation.

Botoff[6] describes a case of obstruction of the bowels with perforation and subsequent peritonitis, in which the post-mortem disclosed 500 ascarides in the bowels.

Simon[7] in an autopsy on a child dead from obstruction of the bowels, found a mass of worms interlaced and strangling the intestines.

In a number of cases reported, the diagnosis of obstruction from worms was made and after the administration of anthelmintics and purgatives a large number of worms passed and the obstruction disappeared.

In other cases, at operation or autopsy, a few worms have been found producing an obstruction. This was due rather to the position of the worms than to the large number mechanically blocking the intestines.

A large lumbricoid has been found in the appendix vermiformis, coiled within the appendix and wrapped around the bowel, producing the constriction.

I find on record very few cases in which the obstruction has been convincingly shown to be due to the mass of lumbricoides.

That a collection of great numbers may be present without producing symptoms of obstruction is mentioned by Winocoucoff[8]. In one case 2,500 were expelled in five months from a child and in another child 12 years old 5,000 were expelled within three years.

Patient.—I saw the child, a boy aged 2½, for the first time at 10 p. m., February 28. The parents stated that he had not been well for some time and that he had worms, having passed eighty in a few days. Careful inquiry convinced me that these worms had merely worked their way out of the child's mouth and anus.

Examination.—In appearance the child was small for his age and very much emaciated. He complained of pain in the abdomen and was restless. The skin was dry and harsh. There was no nausea or vomiting. The child refused nourishment but took water freely. There was no distention of stomach or abdomen. Palpation of abdomen did not show much tenderness. The bowels seemed to be filled with masses, palpable through the thin abdominal wall, which both Dr. F. M. Phillips, who saw the case with me, and myself, thought were worms. The worms forming these masses could be so distinctly felt as to leave no doubt in our minds that they were causing the obstruction.

During the night ten worms came from the patient. We advised operation and the next day the child was brought to the hospital. By this time the stomach and abdomen were distended and on palpation painful.

Operation.—The abdomen was opened in the midline, incision three inches. The abdominal cavity contained a small amount of free bloody serum. The small intestines seemed everywhere filled with worms. Twenty-four inches of the jejunum was distended, almost to the point of rupturing. I opened the bowel and extracted the worms as rapidly as possible. So tightly were they impacted that it was necessary to remove them one at a time until the mass was somewhat untangled. After clearing this portion of the bowels the incision in the bowel was closed. About the middle of the ileum another impaction was found about 10 inches in extent; this was similarly treated. The last point of impaction was found at the cecum. Here the worms were massed in the ileum as well as the cecum and the appendix was so packed that it stood up like one's thumb. It was evident at this time that the bowel had been too largely distended to regain its tone and a resection was considered, but the child's condition did not justify this. No fecal matter was found in any part of the intestines.

Postoperative History.—The abdominal wound was rapidly closed and salt solution given subcutaneously and by rectum. The child was almost pulseless when put on the operating table and died six hours after. In this case the obstruction was clearly due to the large number of worms mechanically blocking and overdistending the bowels. There was no fecal matter anywhere in the bowels, no volvulus, constriction or anything producing the obstruction other than the large masses of worms. The average size of the worms was 9 inches, the smallest 7 inches. Two hundred and seventy-three worms were removed at the time of the operation. Ninety were passed by anus before operating and, as only the masses sufficiently large to produce obstruction were removed, I should think one hundred or more were left in the bowels.

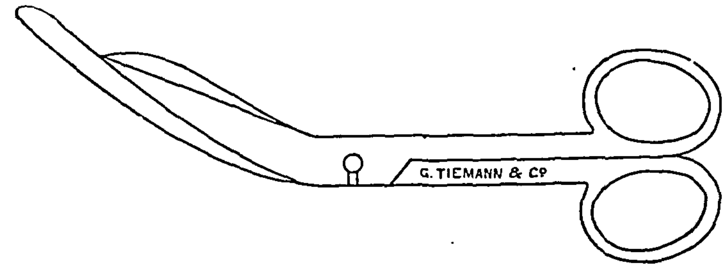
DISSECTING SCISSORS

B. F. JENNESS, M.D.
Passed Assistant Surgeon, U. S. Navy
BUFFALO, N. Y.

This instrument was designed to facilitate the work usually done by a grooved director and scalpel, especially that of enlarging wounds and making incisions where important structures lying beneath the field are not visible. It is particularly useful in enlarging peritoneal incisions, and in hernia work, where the slitting of fascia and aponeurosis necessitates separation from important structures beneath. The tapering steel dissector on the scissor-blade may be pushed beneath tense membranes, and if upward pressure is maintained and the point of the dissector slightly elevated, it will push away the soft tissues beneath, and the structure to be cut will slide on the lower blade of the scissors.



Dissecting scissors.

After a small incision in the peritoneum this instrument can be used to enlarge the cut, without endangering the intestines which may be distended and lying in contact with the peritoneum.

DERMATITIS FROM ARISTOL

HENRY H. AMSDEN, M.D.
CONCORD, N. H.

This case is reported because of my inability to find record of similar disturbance from this drug in the literature at my command.

A. M., aged 27, was delivered March 11, 1910, after normal labor, of a healthy child. There was a superficial laceration of the perineum, closed by silkworm-gut sutures. Aristol was used as a dusting powder, and twenty-four hours later a maculo-papular eruption appeared, affecting principally the extensor surfaces of knees and elbows, thighs and lower back, accompanied by intense itching. The eruption promptly subsided on withdrawal of the aristol; no other probable cause could be assigned for its appearance.

Whether the thymol or the iodin radicle was responsible for the symptoms is a question. It would seem that the common use of this preparation as a local application might not infrequently be followed by dermatitis in susceptible individuals

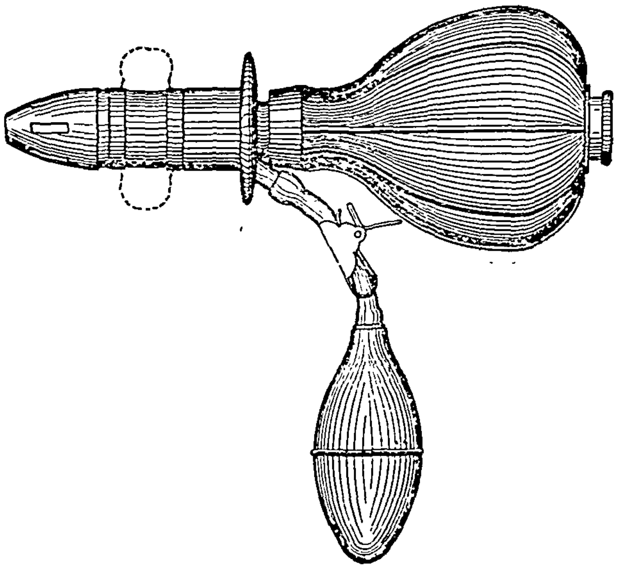
---

A SYRINGE FOR TREATMENT OF CERTAIN VAGINAL DISEASES

S. L. KISTLER, M.D.
LOS ANGELES, CAL.

The syringe shown in the accompanying illustration consists of a nozzle to which is attached a Politzer bag, also a small bulb. The nozzle has surrounding it an inflatable band ring or sleeve and under this band ring the exit of a canal reaching into the small bulb above referred to. The canal leading from the small bulb to the inflatable sleeve has on the small rubber tube a shut-off. The small bulb may be filled with air or other liquid and when it is desired to inflate the ring the small bulb is compressed, which causes distention of the sleeve, and when the cut-off is closed prevents deflation of the sleeve. The Politzer bag attached to the nozzle has an inlet or filling device in its proximal end. A small fountain-syringe or face-bag may be used instead of a Politzer bag, and any desired pressure obtained, according to the height at which the bag is held above the nozzle.

As is well known, germs (particularly gonococci) are prone to penetrate the epithelium and to establish themselves in the deeper layers, even in the submucous tissues, and when so situated a solution injected can have little effect unless pressure is used to produce penetration into the nidi, so that the medicament may be applied directly to the bacilli, or to the tissues in order to hasten repair and thus destroy the germs. Ballooning the vagina is the result of pressure when the instrument shown in the accompanying illustration is used, all crypts and folds being obliterated by the ballooning and the cul-de-sac distended. Consequently the solution is allowed to reach the bacilli directly, a result impossible to obtain with any other syringe with which I am acquainted. Non-staining silver salts are ideal, also colorless hydrastis, zinc and other colorless preparations are recommended for obvious reasons. This treatment is made possible by the water-tight plug or valve which closes the canal and which is the original feature of this device.



Vaginal syringe, consisting of a Politzer bag attached to a nozzle surrounded by an inflatable band ring from which a canal leads into a small bulb. The dotted line shows the vaginal closing device expanded while in use.

3146 Vermont Avenue.

A UNIQUE CASE OF LACERATION OF THE SPHINCTER ANI

A. B. COOKE, M.D.
NASHVILLE, TENN.

History.—Feb. 26, 1910, a boy, aged 7, who lived on a farm, went out to his favorite place behind the corn-crib to attend to a call of nature. While engaged in the act a pet dog, a hound of medium size, came up from the rear and mounting him, effected entrance into the anus and became "accoupled." The child's outcries quickly brought his mother on the scene. The dog had reversed his position and was in the same relation to the boy as is ordinarily seen following sexual intercourse with a bitch. The mother's excitement was naturally very great and in her frantic efforts to disentangle the two she used considerable violence, first with her hand, and finally jerking the dog loose by main strength. When the physician arrived the hemorrhage had practically ceased, but on inspection he discovered that the bowel was lacerated and advised that the boy be taken to Nashville for treatment. He was taken to St. Thomas' Hospital, where I saw him at 10 p. m. the same day.

Examination.—There was no bruising of the surrounding parts and little external evidence of injury. Traction on the anus, however, revealed that several lacerations of considerable extent were present. Under general anesthesia next morning the deepest of these was found to be near the middle line posteriorly, extending from a point two inches up the rectum, through the sphincter muscles and out on the skin surface for a distance of approximately one inch. The external sphincter was torn in two places at this site, one tear being complete, the other partial. Anteriorly there was a second laceration into, but not through, the fibers of the sphincter. In addition there were a number of minor tears in the anal margin involving the superficial tissues only.

Operation.—Fourteen interrupted catgut sutures were used in repairing the posterior laceration and four in the anterior. The others did not require suturing. The result was entirely satisfactory. Union was prompt and complete and the patient returned home in two weeks with perfect sphincter control.

DEXTROCARDIA IN PULMONARY TUBERCULOSIS

RICHARD N. DUFFY, A.B., M.D.
NEWBERN, N. C.

Moderate degrees of dislocation or displacement of the heart not associated with disease of the heart itself are not infrequently seen. Pleuritic effusions, pneumothorax, pulmonary tumors, fibrosis of the lungs, meteorism, peritoneal exudates and transudates and other causes of increased intra-abdominal pressure, all may cause displacement of the heart in various directions depending on the location of the pathologic condition. Again, one may find the heart in an abnormal position at birth in that rare condition known as situs transversus or inversus. By far the most frequent cause of noncongenital dislocations of the heart to the right side, dextrocardia, is pulmonary tuberculosis. Seldom, however, in this disease do we see a complete transposition to the right side.

In a clinical study[1] of 2,344 tuberculosis cases at the Phipps Institute in Philadelphia some degree of displacement of the heart was found in 57 instances, that is, in 2.4 per cent. of the cases. According to Pottenger,[2] however, it is exceptional not to find the heart displaced in advanced pulmonary tuberculosis. In right apical lesions of long standing, according to Brown,[3] even when the physical signs are slight, the right border of the absolute cardiac dulness is not infrequently found three quarters to one inch or more to the right. Turban[4] considers this "a typical and cardinal symptom" of tuberculosis of the right apex. The displacement of the heart in pulmonary tuberculosis may be due to fibrosis consecutive to the tuberculous involvement, to pleurisy with the formation of adhesions, extensive cavity formation, pneumothorax, or a pleuritic effusion.

Complete dislocation of the heart to the right is very uncommon. Only five instances among 2,344 cases examined are reported from the Phipps Institute.[1] The displacement may take place suddenly, owing perhaps to the giving away of slight adhesions, or to sudden changes of intrathoracic pressure. Brown[3] reports a case illustrating the former condition. Or the displacement may be more gradual. Young[5] reports a case of this kind. Brown[3] has also reported an interesting case of valvular pneumothorax from the rupture of the wall of a cavity in the lower part of the left upper lobe, in which the heart was several times gradually forced over to the right side, but always returned when a needle was introduced and the air allowed to escape.

I wish to add the report of the following case to the literature of this subject:

History.—Mr. H., a white man and a native North Carolinian, 43 years old and unmarried, was first seen by me on November 18, 1908, complaining of "consumption." There has been no previous indication of tuberculosis on either side of his family. He has five brothers and all are perfectly healthy. He himself was well up to his eighteenth year when he had a severe attack of measles. This was followed by a pneumonia and a severe diarrhea. He finally recovered from the acute attack but was never strong after this. Four years ago he became very much "run down" and developed a pain in his right chest. He consulted his family physician, was told that he had pulmonary tuberculosis and was advised to go to the North Carolina mountains. This he did and improved slightly. Later he went to Hot Springs, Ark., and here his condition became worse. He was now holding his weight fairly well, but had a harassing cough with profuse expectoration. He had coughed up blood-stained sputum on numerous occasions and had had severe night sweats. He had had an evening rise of temperature to 100-102 F. for several years. Tubercle bacilli had been repeatedly demonstrated in his sputum. About two years before the time of consultation, the patient said, while walking along the street with his hands on his chest he felt his heart beating on his right side. He asserted positively that up to this time his heart had been on the left.

Examination.—The patient was much emaciated and had an almost constant cough. His pulse was 23 to the quarter minute, regular in force and rhythm, of small volume and low tension. His eyes, ears and throat seemed normal. The respirations were rapid and shallow. The intercostal spaces were very prominent and the right clavicle was much more prominent than the left. The respiratory movements of the chest could be well seen on both sides but the movement of the left half of the chest was more marked than that of the right, especially in the upper half. The vocal fremitus was everywhere felt and was especially marked on the right side from the apex to the fourth rib in front. On percussion, the note was slightly dull at the left apex but hyperresonant over the whole of the remainder of the left front and back. On the right side the note was slightly tympanitic at the right apex and infraclavicular region. In the right axilla there was pure tympany down to the fourth interspace and this tympanitic note was also found over the right front, extending from the second to the third rib. The note over the remainder of the right front was dull down to the lower border of the liver. On auscultation, at the left apex the breath sounds were tubular, and fine moist râles were heard at the end of inspiration. Elsewhere over the left front and back the breath sounds were bronchovesicular, but there were no râles. The sounds at the right apex and infraclavicular region were a distant tubular, and over the area of pure tympany the sounds were loudly tubular. Over this whole area were heard râles of all varieties—fine and coarse moist râles, sonorous and sibilant râles. Pectoriloquy was also marked here. Over the remainder of the right lung in front the breath-sounds were a distant tubular and were accompanied by fine and coarse moist râles. The right back was markedly infiltrated throughout. On examination of the heart I was astonished to find the point of maximum impulse just beneath the right nipple. The beat was regular and forcible and there were no thrills to be made out. The area of cardiac dulness extended about 1 cm. to the right of the nipple and above to the third rib in the right mammillary line. It reached its highest point at the second interspace at the right border of the sternum. It then dropped extending across the sternum to the third interspace at the left sternal border. It then curved out about 0.5 cm. to the fourth interspace, then to the right, again reaching the midsternal line at about the fifth interspace, and descending downward and to the right it mingled with the liver dulness. The liver dulness seemed normal in its extent. On auscultation of the heart there was a soft systolic murmur at the apex. This was not transmitted and the sounds elsewhere were normal. There were no signs of circulatory disturbances. The stomach was in its normal position and the abdomen seemed normal throughout.

[4] Turban: Diagnosis of Tuberculosis of the Lungs, 1906.

[5] Young: Boston Med. and Surg. Jour., 1907, clvii, 791.

This remarkable condition seems to me to have only one of two possible explanations. Either there has been a plastic inflammation between the two layers of the pleura and the pericardium with the formation of adhesions and a subsequent retraction of the right lung due to fibrosis; or, there has been a cavity formation in the right lung and a compensatory hypertrophy of the left lung with a crowding of the heart over into this cavity, the sudden dislocation being probably due to the rupture of delicate adhesions. From the history and the physical signs the latter explanation is probably the correct one.

This patient is still living and it has now been nearly a year and a half since I first saw him. It is therefore about three and a half years that his dextrocardia has existed. He still shows no signs of circulatory disturbance of any moment and is apparently as comfortable with his heart on his right side as he was with it on the left.

Therapeutics

DIABETES INSIPIDUS

While diabetes insipidus is perhaps never really a disease and is often a symptom, it may be a more or less permanent condition. Any suggestion as to its cause or any means of diagnosing its cause is of value in directing the treatment. While many times the condition is unimportant, not infrequently it is of serious import.

The condition called polyuria should be separated from the condition to which the above name applies. Hysterical polyuria, nervous polyuria, or the polyuria of excitement, the polyuria of high tension, of arteriosclerosis, and of chronic interstital nephritis is well understood, but generally the amount of urine passed under these conditions is represented by pints, while diabetes insipidus is represented by quarts.

Cerebral irritations and certain diseases of the cerebrum and injuries to the cerebrum have been recognized as factors in producing diabetes insipidus, but the inability of the kidneys to excrete urine of normal specific gravity, necessitating enormous amounts of water excretion to eliminate the salts which must pass out of the body, has perhaps not been recognized.

O. Minkowski (*die Therapie der Gegenwart*, 1910, li i, p. 4) defines diabetes insipidus as any disease in which there is an increased excretion of non-sugar-containing urine, without being accompanied by a lesion of the kidney. It is necessary for the practitioner to distinguish the following: 1. Whether the increased urine excretion is a primary disorder, which would lead to a reduction in the water content of the organism unless large quantities of water were taken. 2. Whether the real cause of the large volume of urine is an excessive thirst accompanied by excessive drinking. 3. Whether one or both of the above are produced by other disorders.

In general, one observes the effect of a great reduction in the water intake on the urine excretion. If the disease is a primary polydipsia, the urine excretion should be reduced by limiting the amount of water drunk. If, on the other hand, the urine volume is not reduced, the inference is that polyuria is the primary disorder. Under the latter conditions the patient will experience an enormous loss in weight, due to the removal of the water from the tissues, especially if the water intake is reduced. In most cases of diabetes insipidus, increase in the specific gravity of the blood and lowering of its freezing-point are avoided by the withdrawal of water from the tissues into the blood. Consequently, these physical properties are of little value in the differential diagnosis.

A number of authors, particularly E. Meyer, have believed in a special functional disorder on the part of the kidney which they describe as "a loss of the ability to concentrate the urine." If this is true, it would be necessary to excrete a large volume of urine in order to remove a large amount of waste from the body, and this would necessitate a large water intake. If the requisite amount of water were not taken, the tissue moisture would be removed else a retention of the solid urinary constituents would occur, resulting perhaps in uremia.

This inability of the kidneys of certain patients to excrete concentrated solutions, is particularly true of solutions of sodium chlorid, and to a lesser extent true of solutions of urea. If such patients receive from 10 to 20 gms. of sodium chlorid (NaCl) with the food, the concentration of the urine in salt is very little increased (from 0.1 to 0.2 per cent.). A large amount of urine and considerable time are therefore necessary for the excretion of all the salt. Minkowski makes use of this fact in differentiating between polyuria due to inability of the kidneys to concentrate the urine, and polyuria dependent on some other factor. If, after giving from 10 to 20 gms. sodium chlorid, the urine of the next twenty-four hours contains practically all of the salt, the individual is placed on a water-poor diet. If very little of the salt is excreted without increasing the water intake, the best treatment is to put the patient on a sodium chlorid, nitrogen-poor diet. In one patient treated by the latter method, there was a reduction in the urine volume from 12 to 14 liters (quarts) to 3 to 4 liters daily.

The diagnosis of the cause of diabetes insipidus having been made, the treatment may be aimed more or less successfully to cure the condition, or to prevent the operation of the cause. A simple polyuria from overdrinking can, of course, be easily prevented. Nervous causes may be modified if there is not actually some pathologic condition in the brain. If the blood-pressure is high, the lowering of it by proper baths, massage, physical exercise, change to a warm climate, diet, or by vasodilators will prevent it. Polyuria may, however, occur with low blood-pressure causing perhaps some disturbance of the brain, as theoretically low blood-pressure should not cause diabetes insipidus. Such instances may be helped by the vasoconstrictor drugs, and especially by ergot. It is possible that this effect of ergot is due to its action in preventing cerebral irritation, cerebral congestion, and possibly the slight cerebral exudate that may occur.

It is obvious that if large amounts of urine are passed, even if the water intake is reduced, that the patient should not be deprived of drinking plenty of water, as otherwise he will extract water from his own tissues to his immediate and perhaps permanent injury. This fact having been ascertained, and the persistent low specific gravity of the urine showing that a metabolic mistake is present in the kidneys, the outcome of the condition is very uncertain. Naturally, a nitrogen-poor and a salt-free diet could not be long persisted in, but each individual patient with this condition should be so carefully studied that he does not lose weight, and then possibly, little by little, the kidney ability to excrete urine of proper specific gravity might be developed. This improvement in the kidneys at times probably occurs. In other words, the physiology of any organ may improve. Whether the administration of kidney extracts or kidney tissue would help this kind of an insufficient kidney has not been demonstrated. It probably should be tried, even though these extracts have not much modified the excretion of nitrogen or prevented uremia in nephritis.

PROTECTIVE APPENDICITIS

So much has been said, and has been said so emphatically and so vociferously, of the necessity for immediate operation in appendicitis, and the conditions found at operation are so many times so much more serious than was anticipated, that it is time to note that there is a group of cases in which operation may be deferred or entirely avoided.

It is especially a pleasure to quote the opinion of one who has been so insistent in preaching the gospel of early operative treatment as Dr. Robert T. Morris, of New York. At the International Medical Congress, at Budapest, last September, Dr. Morris presented his views on this subject. (*Medical Record,* Jan. 8, 1910). He described protective appendicitis as "an irritative lesion, occurring in the course of normal involution of the appendix, and dependent on irritation of nerve filaments which persist in the contracting hyperplastic connective tissue which has replaced other normal structures of the appendix."

This form of appendicitis he distinguishes from another irritative lesion due to serous infiltration of the tissues of the appendix, which is seen in lithemic conditions, in obstruction of the lymph and blood circulation, and in loose right kidney which is said to cause obstruction by pressure on the superior mesenteric vein; and from two forms of infective lesions, one due to intrinsic infection, and the other to extrinsic infection. Morris believes that the most common lesion of the appendix is the irritative lesion which he now proposes to call "protective appendicitis," which he formerly called fibroid degeneration of the appendix, which Senn, in 1894, called appendicitis obliterans, and Ribbert, in 1902, called normal involution of the appendix.

The pathology of this condition consists of a replacement by connective tissue of structures susceptible of acute infective processes, *i. e.,* normal involution of the appendix. Nerve filaments persist longer than most other histologic structures and are irritated by the contracting connective tissue, hence the occurrence of more or less pain. Morris believes that this pathologic process probably is actually protective against local infective processes.

The symptoms of this condition are discomfort in the appendix, of long duration and varying intensity, but not sufficiently severe to cause the patient to go to bed; flatulence; more or less constipation and symptoms of chronic intestinal indigestion.

Among important considerations in the diagnosis of this condition Morris finds hypersensitiveness on deep pressure at the location of the right group of lumbar ganglia, situated about an inch and a half to the right of the navel, and close to the lumbar vertebræ. If there is sensitiveness in this region on both sides of the abdomen, the lesion is probably pelvic rather than appendicular. Another symptom of diagnostic importance is the distention of the cecum and ascending colon with gas, which is more dependent on paralytic relaxation of the muscular coat of the intestine than on fermentation in the intestine. Some observers claim that in most of these cases the presence of an appendix firmer than normal can be determined by palpation.

The treatment depends on the conditions present in each individual patient. If the pain is not severe and the patient is of sufficiently calm temperament not to be annoyed by it, operation need not be advised, and the patient may be told that there is no necessity for the removal of the appendix on the ground of impending danger. His comfort, however, should be increased by such hygienic, dietetic, tonic, and laxative treatment as seems advisable to improve the intestinal digestion. The patient may also be told that his abdominal discomfort will probably gradually be less frequent and finally not recur. If, on the other hand, the discomfort is considerable and continuous, and renders the patient anxious and apprehensive, so that his usefulness is impaired, an operation may be advised, and can be performed with comparatively little danger, certainly with far less danger than by the removal of the healthy appendix, in doing which a point of infection is opened in the midst of an unprepared field.

Radium Ores as Remedies.—In a communication to *Nature,* Nov. 11, 1909, H. Warth suggested that since radium has been found of therapeutic value in many conditions, that pitch blend might also be thus utilized. He says: "The very minute proportion of radium in pitch blend need be no real objection. If we substitute, in the case of pitch blend, grams for milligrams and days of application for so many minutes, a disparity of one million is soon made up, and there may be some action, although perhaps different from that of pure radium salt. Moreover, we must expect a beneficial influence from minute quantities of radioactive substance if the assumption is to be finally proved that certain thermal waters owe much of their virtue to such traces. In addition to raw pitch blend, a possible utility of pure (yellow) uranium oxid might also be considered." In a later number of the same journal (December 16) Antoonovich writes from St. Petersburg and reports that the workmen in a uranium mine which he was developing in Turkestan, where the ore averages from 3.8 to 30 per cent. or more, when cautioned in regard to the poisonous nature of the minerals, claimed that the powdered mineral dusted over wounds caused a much more rapid healing. A cut on the hand, they said, which lasts for a long time in a coal mine, gets well very quickly when powdered by the uranium ore. As they worked part of the year in coal mines they could compare their experiences.

SATURDAY, JUNE 18, 1910

PHOSPHORUS POISONING IN THE MATCH INDUSTRY IN THE UNITED STATES

The recent work by the secretary of the American Association for Labor Legislation, Dr. John B. Andrews,[1] on the occurrence of phosphorus poisoning in this country is a valuable contribution to the study of this form of industrial poisoning. Contrary to a more or less widespread impression, even among physicians and dentists, Dr. Andrews shows that phosphorus necrosis of the jaw in serious form is not at all a rare occurrence among match workers. It is true that manufacturers and others claim that the disease has not occurred to any noteworthy extent in this country during the last twenty years; Andrews, however, was able within a comparatively short time, to unearth the records of more than one hundred recent cases. On account of the peculiar difficulties in the way of securing accurate information, the total number of cases and their proportion to the number of workers probably cannot be precisely determined. We learn that the fifteen factories studied (there are sixteen factories in all in this country) employ about 3,591 persons, so that it is clear enough that phosphorus poisoning in the match industry in this country at present is not an insignificant matter.

Three kinds of matches are made: the safety match which contains no phosphorus and is harmless, the igniting composition, which consists of red phosphorus, and which is harmless when pure, being painted on the box; a strike-anywhere match, the paste in the head of which contains poisonous white phosphorus; and a strike-anywhere match in which the poisonous phosphorus is substituted by the non-poisonous sesquisulphid of phosphorus. The last match has been used exclusively for the last twelve years in France; in this country the strike-anywhere match made with poisonous phosphorus constitutes the principal output.

It is in the mixing, dipping, drying and packing rooms of the factories that the danger from breathing phosphorus fumes and from contact with phosphorus is always present. It is thought that minute particles of phosphorus enter cavities in the teeth and set up the progressive inflammation and necrosis of the bones of the jaws which characterize phosphorus necrosis. Dr. Andrews' study of the actual conditions in the fifteen factories investigated revealed that 65 per cent. of the employees were working under exposure to the fumes of white phosphorus and consequently to the dangers of poisoning; on account of the nature of their employment the women and children are more exposed than the men. Indeed, 95 per cent. of the women and 83 per cent. of the children under 15 years of age were so exposed. Undoubtedly lack of knowledge of the facts must be held responsible, in some measure at least, for the ignorance displayed of the dangers involved and for the neglect in some places to use even the simplest precautions as shown by the absence of means for carrying away the fumes arising visibly from the benches of the workers, by insufficient washroom facilities, lack of mouth washes, etc. In some factories the employers had done nothing to instruct the employees of the dangers to which their work exposed them. During recent years the conditions have been greatly improved by the institution of modern ventilation, improved machinery, better lavatory facilities, etc., but the disease exists and still claims its victims one by one, though not to the same extent as twenty years ago.

Attempts at removing the conditions which bring about "phossy jaw" were begun long ago by various European states, but the disease could not be wholly prevented even when the conditions were greatly improved. This experience has led to the prohibition in many countries of the use of white phosphorus in the manufacture of matches. This was done by Finland in 1872 and in Denmark two years later, since which time no case of phosphorus necrosis has occurred in these countries. More recently the leading European countries have abandoned attempts to suppress by regulation phosphorus necrosis, and now prohibit absolutely the use of white phosphorus in matches (France, 1897; Switzerland, 1898; Netherlands, 1901), and in 1905 the International Association for Labor Legislation secured a treaty providing for the prohibition of the making and selling of matches made of white phosphorus, which treaty has been signed by France, Denmark, Germany, Italy, Switzerland, the Netherlands and Great Britain. The experience of Great Britain is especially noteworthy; twelve years ago a thorough investigation of the conditions was made and stringent regulations, coupled with an efficient inspection, instituted. But "phossy jaw" was not prevented, and in 1908 this country also prohibited the use of white phosphorus.

No American state has yet adequately provided for the protection of workers in match factories, and, everything considered, it would seem clear that the use of a substance of such insidious poisonous action as white phosphorus should no longer be permitted so long as harmless substitutes are available and commercially practicable.

The remedy is to prohibit absolutely the use of white phosphorus in the manufacture of matches, as well as the importation and selling of matches thus made.

---

PRESIDENT-ELECT JOHN B. MURPHY

There are probably but few men in the ranks of American medicine who are better known at home and abroad than the President-Elect of the American Medical Association, Dr. John Benjamin Murphy of Chicago. His work in surgery easily places him in the front rank of American surgeons—which means in the front rank of the surgeons of the world.

Dr. Murphy was born in Appleton, Wis., Dec. 21, 1857. He was reared on a farm, attended the secondary schools and was graduated by Appleton High School in 1876 and by Rush Medical College in 1879. After service as intern in Cook County Hospital, Dr. Murphy formed a partnership with Dr. Edward W. Lee. In 1882 he went to Europe, where he studied in the hospitals of Vienna, Berlin, Heidelberg and London, returning in 1884 to Chicago.

Dr. Murphy has been successively lecturer in surgery at Rush Medical College; professor of surgery in the College of Physicians and Surgeons, Chicago; professor of surgery in the Northwestern University Medical School; professor of surgery in Rush Medical College, and for the second time, professor of surgery in the medical department of Northwestern University, which position he still holds. While Dr. Murphy is known best to the medical profession in general as a surgeon, he is known to an increasingly large portion of the profession as an instructor of the highest rank. He is a born teacher and not only has a message to give but possesses in a marvelous degree the power to give it.

JOHN B. MURPHY, M.D.

As a surgeon Dr. Murphy is typical of the country; not content blindly to follow precedent, he has blazed new trails. And, what is of even more import, in attacking a problem he is not content to leave it half-solved, in a formative stage as a mere interesting academic possibility; when it is perfected he has a fully developed, practical method, given as a complete procedure to his contemporaries. In this particular Dr. Murphy stands unique; he has not only invented, he has perfected.

Some of the best-known of Dr. Murphy's writings are: "Cholecysto-intestinal, Gastro-intestinal, Entero-intestional Anastomosis and Approximation Without Sutures;" "Ileus;" "Resection of Arteries and Veins Injured in Continuity;" "Surgery of the Lungs;" "Operative Surgery of the Gall Tracts, with Report of Twenty Successful Cholecysto-Enterostomies by Means of the Anastomosis Button;" "Fracture of the Olecranon Treated by Subcutaneous Exarticular Wiring;" "Surgery of the Spinal Cord and Peripheral Nervous System:" "Tuberculosis of the Patella;" "Proctoclysis in the Treatment of Peritonitis."

As a progressive and aggressive member of the medical profession no less than as a leading educator and a surgeon of high rank, Dr. Murphy honors the office to which he has been elected.

THE ST. LOUIS SESSION

The St. Louis Session of the American Medical Association was an unqualified success. From the scientific point of view, and from the effect in the promotion of a closer and more harmonious organization of the profession, as well as of social interest, little more could have been desired. The registration was a little over four thousand, a number exceeded only twice—at Boston and at Chicago.

In the scientific interest and in the earnestness and fulness of the discussions on the topics presented the section meetings equaled or surpassed those of any previous session. Every section had profitable meetings and the attendance in each was good. Especially notable were the symposiums in the Section on Preventive Medicine and Public Health on hookworm, pellagra and typhoid fever, and in the Section on Pathology and Physiology on cancer—subjects which, aside from their interest to the profession, have particular interest for the public, because of the wide-spread morbidity and mortality which they cause, especially in the instances of typhoid fever and cancer. Indeed, it is interesting to note the many points at which the papers throughout the whole program of this session touched the public directly in the matter of hygiene, sanitation and prevention. It is a reflection of the wide-spread interest of the public in what is being done in medicine. In many respects the Section on Preventive Medicine was the most interesting of the Session. Cancer, with its frightful mortality and increasing prevalence, was probably the most prominent subject of the Session, being considered in one or more of its aspects in almost every section, far outshadowing tuberculosis in this respect. In some of the other sections symposiums on diabetes, the infectious diseases and eclampsia, with the discussions, served to clear the atmosphere about many mooted questions. There were many other interesting features of the scientific program, but space forbids further mention of them here.

The meetings of the House of Delegates were harmonious throughout. Each succeeding year the reference committees are doing more and more work, making it possible to investigate thoroughly all the various propositions that come before the House; and thus the House is able to accomplish much more, and to do the work in a deliberate, satisfactory manner. Of the important things done by the House of Delegates, one was the creation of a new Section on Genito-Urinary Diseases, as petitioned for by many members doing work in that line. Another was the creation of the Council on Health and Public Instruction, which is to have charge of the work formerly done by several overlapping committees, covering such matters as preventive medicine, medical legislation, economics, public instruction in medical, sanitary and hygienic questions, etc. The Council will organize complete machinery to facilitate the attainment of these objects.

Any impression that there was the slightest lack of harmony in the organization was dispelled by the work of the House of Delegates and by the spirit shown in the daily work; and any attempted disparagement of the aims and purposes of the American Medical Association was silenced by the splendid statement of them contained in the address of President Welch at the General Meeting. That the public correctly understands these aims and endorses them was evinced in the admirable address of Governor Hadley and the other gentlemen who spoke at the General Meeting.

The arrangements for the entertainment of the visitors—barring those for Wednesday afternoon, when the rain interfered—were admirably carried out. The pervasive quality of hospitality, the geniality and cheerful friendliness of the South, which are characteristic of the people of St. Louis, were in evidence. The physicians and their wives and daughters were delightfully entertained at the President's reception and at many dinners and luncheons. The school and class reunions were also occasions affording pleasure and satisfaction to those participating in them.

The arrangements at the various section meeting-places were declared by some to be a distinct advance over anything heretofore seen, and the local subcommittee in charge of these arrangements deserves the highest praise. Nothing was overlooked which would minister to the comfort and convenience of the members or which would facilitate the smooth running of the sessions. The meeting-halls were models, and telephones, stenographers, messengers and everything needed were provided. A member of the committee was always in attendance to see that nothing was lacking.

The Scientific Exhibit and the Commercial Exhibit, in the Coliseum, in harmony with the rest of the Session, were a complete success. The Scientific Exhibit in the balcony, though not so accessible, perhaps, as could be desired, was interesting and well attended. The demonstration of the hookworm, for which Smith of Atlanta was given the prize, was especially attractive. Worthy of particular note was the exceedingly interesting and valuable exhibit of the St. Louis Historical Society adjoining the Scientific Exhibit. A feature of the balcony exhibit was that of the Association Laboratory, in the exposé it made of a number of well-advertised nostrums, in furtherance of the work which the Council on Pharmacy and Chemistry is doing. It elicited much favorable comment from visitors and the graphic way of presenting matters caused surprise to many.

In the interest displayed in the purely scientific subjects, in the practical subjects, in the matter of preventive medicine as touching the public and the general welfare, and in the association as an organization having the highest aims and the most altruistic purposes, the St. Louis session was a notable milestone in the gratifying progress of the American Medical Association.

INDUSTRIAL HYGIENE

Three important national conferences, one on industrial accidents and workmen's compensation, one on industrial diseases, and one on labor legislation, were held on June 10 and 11 in Chicago; and many important bodies were represented in the discussions. It is earnestly hoped and expected—and the expectation is reasonable—that by means of these conferences and the resulting coordinated activities, great and salutary changes will be achieved in the conditions to which people working in trades are subject.

Of these conferences, that on industrial diseases was the first ever held in this country. The interest which the medical profession should take in this subject was well indicated by Mr. Frederick Hoffman, actuary of the Prudential Insurance Company, of Newark, N. J., who declares that in many trades one-third of the deaths recorded are due to one specific disease; and that, at a conservative estimate, the money loss alone in the United States in one year, due to preventable occupational disease, is nearly a billion dollars. (Another statement made at this conference was that the money loss alone in the United States in one year due to sickness cost, loss in wages, and economic loss in industry, may be conservatively placed at a billion and a quarter dollars.)

Mr. Hoffman continues: "Medical practitioners will realize some day the practical advantage of special knowledge of diseases of occupation;" and it is exceedingly gratifying to note his assurance that the truth requires only to be known to produce a remedy for intolerable or needlessly injurious conditions. "Employers of labor are now doing much to ameliorate conditions. An awakened public conscience is at last being aroused. It is the duty of those qualified to do so (such as physicians) to ascertain the truth of industrial conditions affecting the physical well-being of American wage-earners."

The need of wider interest in the health problems of modern industry was also expressed on this occasion by Dr. Henry B. Favill of Chicago: "It is pretty nearly axiomatic that the modern labor problem is a health problem." Careful investigations should be made by men trained both in physiology and economics, so that effective means may be forthcoming for the prevention of the human waste in industry. Thousands suffer and die yearly from preventable occupational diseases, as for example, in those industries which make use of poisons, such as yellow phosphorus, still employed in this country, though harmless substitutes for it have long been employed in Europe.

It would appear, from the viewpoint of the general practitioner, if from no other, that no anamnesis is complete without an exhaustive consideration of the patient's occupation (which, indeed, cannot be adequately appreciated unless the physician has more than a casual and superficial understanding of the actual working conditions); nor is any plan of therapy likely to succeed which does not take into account a healthful environment during the patient's working hours.

ADDED ENDOWMENT FOR WESTERN RESERVE

Announcement has just been made of a gift of $250,000 to Western Reserve University, by Mr. H. M. Hanna, as an addition to the endowment of the medical department. It is intended that the income from this gift shall be used largely to place the various clinical professorships on a modern university basis. This gift is very opportune, coming as it does with the news that the consolidation of the Cleveland College of Physicians and Surgeons with the Medical Department of Western Reserve University has been consummated.

AMERICAN SURGERY—AN APPRECIATION

Europeans who have made a study of commercial life in the United States maintain that the fundamental difference in methods between the American and the European is one of mental attitude. With the European the tendency is to adhere to, or at most to modify, the old; with the American, to attempt what is altogether new. The European engineer prides himself on the fact that his machinery is so well made and so carefully preserved that it will last a generation; the American engineer on the other hand does not hesitate to relegate to the scrap-heap the most elaborate piece of machinery the moment a more efficient piece is invented to take its place. That this progressive attitude is not confined to mechanics and commerce in America is evidenced by the observations recently made in the *Practitioner,* by a London surgeon, Mr. W. Arbuthnot Lane of Guy's Hospital. In contrasting the skepticism of British surgeons with the attitude of the surgeons of the United States and Canada he says: "They are in advance of us in many ways in their methods of investigation. They attack any new problem very thoroughly and do their utmost to verify every fact by personal observation and they determine whether there is any truth in it or not. Trouble or expense affords no obstacle to their thirst for knowledge. They are not satisfied to accept unreservedly any statement or observation, and least of all, any opinion, and they are only prepared to receive it when they themselves have either seen it or are satisfied as to its accuracy. They have no respect for so-called authority and part with innumerable surgical creeds which continue to control us as readily as their business men 'scrap' machinery the moment a better mechanism is devised. It is this attitude of the American surgeon that is exerting such a magnificent influence on the surgery of that country and is, in my opinion, making them the most progressive surgical body in the world." Mr. Lane of course has been in the United States and evidently speaks from observation.

THE NEW YORK COCAIN LAW

During the last session of the New York legislature a particularly vicious amendment was made to the penal law of that state relating to the sale of cocain or eucain. As the law now stands the druggist must give to every person who presents a prescription in which cocain or eucain or their salts are ingredients a certificate worded as follows:

..................191

This is to certify that the bearer obtained from me on the above date, upon the written prescription of
....M.D.
of..
...... grains of cocain or eucain.

This certificate is furnished in conformity with the Act Amending the Penal Law of New York State in relation to the sale of cocain or eucain, enacted April, 1910.

Druggist, ...
....
Registered Pharmacist.

This prescription cannot be refilled nor copy given.

What the object of such an amendment is, it is hard even to guess; what the results must be is evident. The patient is at once informed of the fact that he is taking cocain—a fact that the conscientious physician is usually careful to conceal. Such a certificate in no way prevents the prescribing of these drugs by renegade physicians to cocain habitués but it does possess enormous potentialities for harm in the making of habitués. Any law that will prevent the misuse of valuable but dangerous drugs is to be welcomed but such laws must be drawn up by those who have at least a working knowledge of the many points involved. As the New York law now stands it not only does not prevent the misuse of cocain and eucain but may easily be the means of leading to the abuse of these valuable but potent drugs.

Medical News

CONNECTICUT

State Medical Society Meeting.—The one hundred and eighteenth annual meeting of the Connecticut State Medical Society was held in New Haven, May 25 and 26. Secretary Anson Phelps Stokes, Jr., of Yale University, stated that $2,000,000 would be necessary to make a first-class school of the Yale Medical School, and asked the aid of the Connecticut physicians in raising this amount. The following officers were elected: President, Dr. Frank K. Hallock, Cromwell; vice-presidents, Drs. Edmund P. Douglass, Croton, and Edward T. Bradstreet, Meridian; secretary, Dr. Walter R. Steiner, Hartford (reelected), and treasurer, Dr. Joseph H. Townsend, New Haven (reelected).

Personal.—Dr. Charles A. Goodrich has been elected secretary and Drs. Marcus M. Johnson and Joseph E. Root have been elected members of the executive committee of the Hartford Dispensary.——Drs. Nicola Mariani and Dr. William Francis Verdi, New Haven, have been made Chevaliers of the Crown of Italy.——Dr. Arthur J. Wolff has been reappointed bacteriologist of the health board of Hartford, and Drs. Alfred M. Rowley, Robert S. Starr, John F. Rooney and David J. Molumphy have been elected medical inspectors.——Dr. William H. Carmalt, New Haven, has been elected councilor of the New Haven County Medical Society.——Dr. George H. Knight, Lakeville, has been elected a member of the Board of Directors for the Establishment of County Homes for the Treatment of Tubercular Patients, to fill the unexpired term of the late Dr. John P. C. Foster, New Haven.——Dr. Herbert E. Smith, after 25 years' service as dean of Yale Medical School, New Haven, has resigned.——Dr. Emilio G. Sera, New Britain, has returned from Europe.

IDAHO

New Member of State Board.—Dr. George H. Coulthard, Idaho Falls, has been appointed a member of the State Board of Medical Examiners.

Society Meetings.—The Idaho County Medical Association was organized at Grangeville, May 27, and the following officers were elected: President, Dr. C. S. Busey, Clearwater; vice-president, Dr. John D. Shinnick, Cottonwood, and Secretary-treasurer, Dr. Carl W. Slusser, Grangeville.——At a recent meeting of the Southern Idaho Medical Society, held in Caldwell, Dr. C. L. Dutton, Meridian, was elected president; Dr. John W. Gue, Caldwell, vice-president; and Dr. Robert L. Glase, Boise, secretary.——Twin Falls Medical Association held its annual meeting in April in Twin Falls, and elected Dr. Walter F. Pike, president; Dr. John Coburn, vice-president, and Dr. James S. Purdy, secretary-treasurer.

ILLINOIS

Hospital Dedicated.—The new St. Francis Hospital, Evanston, erected at a cost of $150,000, was dedicated by Archbishop Quigley, May 28, with impressive ceremonies.

School Named for Physician.—The new school being erected in the west part of Champaign is to be named the Howard School in honor of the venerable Dr. Hartwell C. Howard, who has practiced medicine in that city for more than sixty years.

Openings for Hospital Positions.—Civil service examinations will be held throughout Illinois, July 7, to secure assistant physicians in the insane hospital and other state institutions. It is necessary to apply to the State Civil Service Commission, Springfield, before July 1.

Physician Found Guilty.—In the case of Dr. Benjamin A. Arnold, Freeport, charged with making an attack on a young girl, on whom he had operated for appendicitis, and in which the jury rendered a verdict of guilty in April, the defendant is said to have been sentenced, May 27, to imprisonment for four years in the penitentiary. An appeal is to be taken to the supreme court.

Personal.—Dr. John A. Koch and wife, Quincy, have sailed for Germany.——Drs. Oliver Hughes, Elmer Erickson, Isaac F. Freemmel, interns at Elgin State Hospital, have passed the examination for assistant physicians.——Dr. Thomas R. Foster, assistant physician at the Elgin State Hospital, has been appointed first assistant at the Watertown State Hospital.——Dr. P. S. Weidman, Edwardsville, said to be the oldest practitioner in Madison county, was seriously injured in a fall from his chair, June 2.——Dr. Elbert J. Clark, Rockford, has succeeded the late Dr. George W. Rohr as district pension examiner.

Chicago

Emergency Work in Hands of Police.—The removal of the ambulance and hospital service from the health department to the police department was accomplished June 1, under the direction of Dr. George C. Hunt. Eleven ambulances and sixteen surgeons are connected with the service and headquarters will be in the office of the chief of police.

Golden Jubilee.—Sister Mary Raphael, superintendent of Mercy Hospital for forty-one years, celebrated the fiftieth anniversary of her taking of vows, May 30. Dr. John H. Hollister, the only surviving member of the original staff of Mercy Hospital, Dr. John B. Murphy, and President A. W. Harris of Northwestern University, were the principal speakers.

Personal.—Dr. and Mrs. Emanuel J. Senn, Dr. and Mrs. Henry B. Thomas, Dr. and Mrs. George S. Isham and Dr. S. C. Stanton have sailed for Europe.——Dr. and Mrs. Sidney McCallin were seriously injured in an automobile accident, June 9.——Drs. William L. Baum and Charles L. Mix have been appointed members of the commission to take charge of the work of preparing plans for the rebuilding of the Cook County Hospital.

Commencement Exercises.—At the annual commencement exercises of Northwestern University Medical School, May 31, a class of 150 was graduated.——On May 28, the annual commencement exercises of the College of Physicians and Surgeons, the College of Medicine of the University of Illinois, were held June 7, when the degree of doctor of medicine was conferred on a class of 131. President Edmund J. James of the University of Illinois delivered the doctorate address.

The Latest Diploma Mill.—Dr. Alexander C. Chittick, whose license to practice medicine is said to have been revoked by the State Board of Health, May 24, for unprofessional conduct in connection with the sale of diplomas from the Chicago Medical University and Crescent Medical University, and who was indicted by the grand jury, June 2, is said to have agreed to plead guilty to the use of the mails to defraud, provided a two months' sentence was imposed. The judge ordered the plea of guilty withdrawn and continued the case to June 20.——In the case of Norbert O. Bourque, a graduate of the National University, charged with a similar offense, action was deferred by the State Board of Health, pending the obtaining of further evidence. This individual is said to have signed one diploma, but alleges that he did not know what he was doing.

MARYLAND

Personal.—Dr. James T. Johnson has been appointed secretary of the Cumberland City Board of Health.——Dr. John E. Sanbury, Forestville, has been re-elected health officer of Prince George county.

Board Forced to Reciprocate.—By the recent decision of the District of Columbia Court of Appeals, noted in the *Bulletin of the Medical and Chirurgical Faculty of Maryland*, the action of the Washington Board of Medical Examiners in refusing Dr. Louis B. Thompson, a Maryland physician, a license to practice in the District of Columbia, was declared arbitrary, and license has been issued by application of the court. The application of Dr. Thompson was originally denied by the board on the ground that the examination of the Maryland board was not equivalent to that of the District of Columbia. The court, however, declares that "equivalent conditions exist under the statute by virtue of the provisions of the law, and not under the rules and regulations of the board, as is claimed." A similar suit for a reciprocal license from the District Board instituted by Dr. Henry H. Hazen in March, 1909, was decided in the same way.

Home for Widows and Orphans.—In December last, the foundation of a home for widows and orphans of medical men by the Medical and Chirurgical Faculty of Maryland, was noted. Unanimous action was taken, and a board of managers, consisting of twenty-four persons, was appointed. The board proceeded to adopt active measures to raise funds to inaugurate the home, one of which was application to the legislature. The society would not permit this on the ground that it might jeopardize the application of the society for an appropriation to pay off the debt on the new building. This dispelled the prospect of an early opening and deprived the board of a large part of the support on which it relied. At the annual meeting of the society, a committee, consisting of Drs. William H. Welch, William S. Thayer and William S. Gardner, was appointed to report on the home project, and after taking legal advice, reported that the charter of the society gave no authority for the project, and recommended that the resolution of December 16 be rescinded. This was done and a motion was also voted down, having for its object the securing of legal sanction for carrying on the home. The board of trustees, however, was not willing to abandon the project, and decided to continue the organization under an independent state charter. Mrs. Eugene F. Cordell, president of the board, announces that while the "Fund for the Relief of Widows and Orphans" still remains in the hands of the state society, and is limited to its membership, the "Home," has become divorced from it, and will be conducted hereafter independently and for the benefit of the entire medical profession.

Baltimore

Honors for Porto Rican.—Miss Palmira Gattell, daughter of the head of a drug firm in Porto Rico, won the gold medal for superior scholarship at the Woman's Medical College. She will practice in San Juan.

Alumni Meeting.—The annual meeting of the Alumni Association of Baltimore Medical College was held May 2 and the following officers were elected: President, Dr. James M. Delevett; vice-president, Dr. James E. Poulton; secretary, Dr. John A. Evans, and treasurer, Dr. Harry E. Peterman.

Portrait of Dr. Osler.—A bronze relief portrait of Dr. William Osler has been placed in Osler Hall of the Medical and Chirurgical Faculty. It is by F. C. V. de Vernon, a French sculptor, and is an enlargement of a small one made in 1903 by the same artist and now in the Johns Hopkins Medical Library. It will be placed by the side of the Osler portrait by Corner on the north wall, and on the other side will be hung the Welch medallion.

Personal.—Dr. Ira Remsen, president Johns Hopkins University, sails for Europe June 14.——Dr. Claribel Cone sailed for Germany May 26.——It is reported that Dr. Harvey W. Cushing has been offered and has accepted a position in Brigham Hospital, Harvard University.——Dr. Charles E. Simon has sailed for Switzerland.——Dr. Edward Hume and family have returned to their station in Changsha, China.——Dr. Frank C. Bressler has sailed for Europe.——Dr. George W. Dobbin, who was recently injured in an automobile collision, is reported to be convalescent.

Dr. Cushing's New Appointment.—It is officially announced by the trustees of the new Peter Bent Brigham Hospital at Cambridge, Mass., that Dr. Harvey W. Cushing, of Johns Hopkins Hospital, has been appointed chief of the surgical staff. He will not leave Baltimore until the completion of the hospital, about two years hence.——Dr. E. Deichmann, principal of the Deichmann College Preparatory School, has been reappointed state examiner for the medical, dental and pharmaceutical colleges of this city (except Johns Hopkins Medical School, which requires an A.B.). Henceforth formal written examinations will be held in the school building in August, September and October.

Commencements.—The Woman's Medical College held its twenty-eighth annual exercises May 30, graduating a class of six. President Eugene A. Noble of Goucher College delivered the address.——Maryland Medical College held its annual commencement exercises May 30. Dr. Joseph L. McLaughlin of New Hampshire received the gold medal for scholarship.——Baltimore Medical College held its twenty-ninth annual commencement exercises May 26, graduating a class of fifty-four. The Hippocratic oath was administered by President Charles G. Hill of the college and the announcement of graduates was made by Dean David Street.——The University of Maryland held its one hundred and third commencement June 1. There were 241 graduates, viz.: St. John's (arts and sciences), 17; medicine, 85; law, 60; dentistry, 54; pharmacy, 25. Hon. Henry B. Macfarland of Washington, D. C., delivered the address. The honorary degree of LL.D. was conferred on Dr. Henry R. Carter, U. S. Public Health and Marine-Hospital Service, a graduate of the year 1879.——At its thirty-eighth annual commencement, June 2, the College of Physicians and Surgeons graduated 66, Prof. William T. Councilman, of Harvard University, delivering the address to the graduates. Those receiving gold medals were: Roy W. Locker, Ohio; Harris Goldman, Maryland; William B. Hunter, West Virginia; W. D. Blankensmith, Ohio. Dr. Charles E. Simon has been elected professor of clinical pathology and experimental medicine.——At the commencement of Johns Hopkins University, June 14, the degree of M.D. will be conferred on 68 graduates. The German Ambassador will deliver the address to the g uates.

NEW YORK

Reciprocity With New Jersey Denied.—Owing to the lowering of the standard of preliminary education required for admission to the medical schools of New Jersey, they being below the standard required for admission in New York State, the Board of Regents annulled the reciprocal relations between New Jersey and New York.

Antitoxin for Tetanus.—There are annually one hundred deaths in this state from tetanus as the result of accidents, the majority of which are due to Fourth of July celebrations. Health Commissioner Porter has issued a notice to local health officers urging them to procure from the state a supply of tetanus antitoxin for use in emergencies.

City Can Bar Up-State Milk.—A suit against the New York City Board of Health to recover damages because the plaintiff's milk was rejected at the Cold Spring Creamery, which alleged that it was unfit for consumption, has been decided in favor of the New York Board of Health. The judge held that the New York City Board of Health had absolute jurisdiction without as well as within the city lines, and could impose whatever rule and regulations its officials wished, and compel their observance under penalty of prohibiting the sale of dairy products shipped to New York for consumption as food. It is said that the dairymen will appeal the suit.

Personal.—Dr. Edgar A. Vander Veer, Albany, has succeeded Dr. Irving S. Haynes, New York City, as a member of the Medical Board of the Champlain Valley Hospital.——Dr. and Mrs. William H. Montgomery were given a dinner by the staff of the Willard State Hospital, May 10, on the occasion of Dr. Montgomery's transference to the Long Island State Hospital, King's Park, where he becomes second assistant physician.——Dr. Robert S. MacDonald, formerly first assistant physician to the Dannemora State Hospital, has opened an office in Plattsburgh.——Dr. Edward G. Cox, Albany, was injured in an automobile accident near Loudenville, May 25.

State Board of Regents Makes Appointments.—Dr. William Warren Potter and Dr. Lee H. Smith, Buffalo, and Dr. Glentworth Reeve Butler, Brooklyn, have been appointed on the State Board of Medical Examiners; Prof. James Law, Ithaca, Dr. C. F. Greenside, New York, Dr. R. C. Reed, Elmira, Dr. H. S. Beebe, Albion, and Dr. George A. Knapp, Millbrook, have been appointed on the State Board of Veterinary Examiners; Dr. A. M. Holmes and Dr. H. H. Burkhart have been reappointed and Dr. E. C. Parker of Poughkeepsie, appointed on the State Board of Dental Examiners; Charles F. Prantice and George R. Fox have been appointed examiners in optometry.

Bills Signed by the Governor.—The bill lowering the standard of milk so that it shall be considered adulterated when it contains less than 11½ instead of 12 per cent. of milk solids.——The bill providing that when a convicted murderer appears insane, the Governor may appoint a commission of three to examine him and to report to the Governor, whereupon, if found insane, the Governor may order his removal to a state hospital for insane convicts, where he shall be kept in custody until cured of his insanity, when, on an order of the justice of the supreme court, the convict is to be returned to the warden of the state's prison to suffer the sentence given him under the law.——A bill signed by Governor Hughes creates a new State Board of Pharmacy of nine members, to be appointed by the State Board of Regents, to take the place of the present board of fifteen members. This law is favored by the State Pharmaceutical Society and establishes a standard for drugs and medicines.

New York City

Women Physicians Dine.—The alumnæ of the New York Women's Medical College held their annual dinner at the Hotel Manhattan on the evening of June 1.

Measles on Ocean Liner.—The Cunard steamer, Pannonia, arrived from the Mediterranean, May 26, with more than twenty cases of measles on board. The patients were removed to Hoffman's Island.

Professional Building.—The Herald Square Health Co. is about to erect, on a lot 40x102 feet off West Seventy-first street, an eight-story building to be devoted entirely to the use of physicians and dentists.

Berlin Professor to Lecture in New York.—Dr. E. Grawitz, ssor of pathology in the University of Berlin, will deli ress in English before the New York Academy of icine on "The Definition of Pernicious Anemia and its Treatment."

Summer Home Opens.—The Association for Improving the Condition of the Poor has opened the Sea Breeze Home. By the middle of the month the Home will be filled to the fullest capacity. The cost of maintaining this resort is $90,000 for the season.

Death-Rate Drops.—The week ending May 20 showed a decrease in the death-rate from the corresponding week of 1909. The rate for 1909 was 16.76, while for 1910 the rate was 16.10. Pneumonia and heart disease caused fewer deaths than last year, while diphtheria caused more.

Personal.—Dr. and Mrs. Thomas E. Satterthwaite have sailed for Europe.——Dr. Maurice H. Gross has opened an uptown office in the Sydenham Building.——Dr. Abraham L. Wolbarst has been appointed delegate from the Peace Society of New York to the eighteenth International Peace Congress, to be held in Stockholm, Sweden, August 1 to 6.

Hospital Outgrows Quarters.—The German Hospital, situated at St. Nicholas avenue and Stanhope street, has been forced to authorize the construction of an annex that will cost $25,000. The proposed annex will provide for three wards and will be ready for occupancy in about three months. The funds for the increased expenses of the institution have not yet been provided, but the Hospital Benefit Society is preparing a benefit.

Equality League Branch Formed.—At a meeting held in Belmont Municipality Hospital, Hempstead, L. I., May 23, the woman physicians' and surgeons' branch of the Political Equality League was formed with the following twelve charter members: Drs. Jennie V. H. Baker, Brooklyn; Mary E. Pelton, Anna H. Shaw, Mary L. Lines, Brooklyn; Mary E. Fish, Sophie B. Scheel, Brooklyn; Cornelia C. Brant, Brooklyn; Mary Halton, Harriet Van Buren Peackham, Brooklyn; Harriet W. Hale, Brooklyn; Rachel R. Nottage, Brooklyn, and Kate MacLaren, Borough of Queens.

PENNSYLVANIA

King Edward Memorial.—At a meeting held at Pittsburg, June 5, $25,000 was subscribed towards erecting a memorial to the late King Edward VII. The building to be erected is to be a part of the proposed tuberculosis hospital of Pittsburg.

Memorial Annex to Hospital.—The Board of Managers of the Chester Hospital has accepted an offer from Mrs. Charles B. Houston to erect a building in connection with the hospital to be known as the "C. B. Houston Children's Ward," in memory of her deceased husband.

Personal.—Dr. W. T. Miller has returned to take up his permanent residence in McKeesport.——Dr. Ehlers, an assistant resident physician in the male department of Norristown State Hospital, has resigned.——Dr. Rothe has been appointed intern for the female department of the hospital.

Sanatorium Favored.—Dr. Samuel G. Dixon, State Commissioner of Health, sent a letter approving the action of the Central Poor Board of Wilkes-Barre in arranging to build a sanatorium for caring for the indigent victims of tuberculosis. The work will not interfere with the activity of the state in the same direction.

Philadelphia

Polyclinic Faculty Changes.—Dr. John H. Jopson was elected professor of surgery; Dr. Wendell Reber, professor of ophthalmology, and Dr. William Zentmayer, extramural lecturer in ophthalmology. With the exception of these three changes the faculty of the institution will remain the same as last year.

Jefferson's New Laboratory.—Jefferson Medical College has purchased the old building of the Pennsylvania Dental College at Eleventh and Clinton streets, for a consideration of $47,500. The lot is 40 by 116 feet with a lot in the rear 40 by 60 feet. No important changes will be made in the building for the present and it will be used as a laboratory.

Museum Grounds Transferred.—An ordinance passed by the common and select council gives the University of Pennsylvania the possession of a large tract of land along the western shore of the Schuylkill river, south of Pine street. The grounds and buildings at present are occupied by the Commercial Museum of Philadelphia, who are to remain in possession until the city provides another site for the museum. The University in return is to give the city seventy-five scholarships annually, the distribution of which rests with the mayor of Philadelphia.

Medico-Chirurgical Alumni Banquet.—The annual banquet of the Medico-Chirurgical College was held in the Bellevue-Stratford, June 2. About 400 men were present and Dr. John Egan presided. Addresses were made by Hon. Henry F. Walton, president of the board of trustees; Dr. J. W. Holland, dean of Jefferson Medical College; Hon. Edwin S. Stuart, governor of Pennsylvania; Hon. John Reyburn, mayor of Philadelphia; Dr. Ernest LaPlace and Mr. A. E. Hetherington. The following officers were elected: Dr. C. T. Faries, president; first vice-president, Dr. Edward Guyon; second vice-president, Dr. W. A. Sears; third vice-president, Dr. E. F. Bickel; secretary, Dr. E. H. Erney; treasurer, Dr. E. S. Gans.

Rush Hospital Addition Open.—The completed portion of the Rush Hospital for the treatment of consumption, was opened for the inspection of the public, May 21, and opened for patients, May 23. This hospital was one of the first in the country for treating tuberculosis, and beside its city plant has a country branch at Malvern, Pa. Facing on Thirty-third street, the new addition contains administration rooms, dispensaries, an apothecary shop, nurses' quarters and rooms for private patients. The building is finished in the most approved hospital style, without corners. At present the addition is but two stories, but when completed (when sufficient funds are raised) will be four stories.

Jefferson Alumni Banquet.—The annual banquet of the Alumni Association of the Jefferson Medical College was held in the Bellevue-Stratford, June 4, with nearly 500 men present. Dr. J. M. Fisher presided and addresses were made by Dr. S. Weir Mitchell, who this year celebrates the sixtieth anniversary of his graduation from this institution; Hon. Edwin S. Stuart, governor of Pennsylvania; and Dr. Lawrence F. Flick, who spoke for the alumni. A special feature of the meeting was the presentation of an oil portrait of Hon. William Potter, president of the board of trustees. The presentation was made by Dr. J. Chalmers Da Costa and accepted by Mr. Simon Gratz, secretary of the board. At the same time a large silver loving cup was presented to Mr. Daniel Baugh, a member of the board of trustees, by the hospital staff, in recognition of his services as chairman of the hospital committee. The cup was presented by Professor H. A. Hare.

College Commencements.—The eighty-fifth annual commencement of the Jefferson Medical College was held at the Academy of Music, June 6, 1910. The graduates numbered one hundred and forty-two, and received their diplomas from Hon. William Potter, president of the board of trustees. Three features of the commencement made it especially notable. A glowing tribute to the memory of Professor Samuel D. Gross was made in an address by Dr. William W. Keen, and announcement was made of the endowment of a chair in surgery by Mrs. Maria Gross Horwitz as a memorial to her father, to be known as the Samuel D. Gross chair of surgery. Professor J. Chalmers Da Costa was elected to fill the position. The degree of LL.D. was conferred on Dr. S. Weir Mitchell, marking the occasion as the sixtieth anniversary of his graduation from the college. A portrait of the dean of the college was presented to the trustees by Dr. William L. Rodman in behalf of the Alumni Association. An oil portrait of Dr. J. W. Holland, dean of the college, was presented to the Board of Trustees by the Alumni.——The thirtieth annual commencement of the Medico-Chirurgical College was held in the Academy of Music, June 3. Eighty-four men received diplomas and the annual address was delivered by Hon. David J. Foster, of Vermont. Forty-nine hospital appointments were received by members of the graduating class.——The annual commencement of the Women's Medical College of Pennsylvania was held in the Academy of Music, June 2. Thirty women received degrees and the address to the class was made by Dr. Ira Remsen of Johns Hopkins University.

VIRGINIA

Commencement Exercises.—The seventy-second annual commencement exercises of the Medical College of Virginia, Richmond, were held May 18. Dr. Simon Baruch, New York City, delivered the address before the alumni association, "The Therapeutic Lesson of Half a Century," and President Lyon G. Tyler of William and Mary College gave as his commencement address, "Medical History of the State from 1607 to the Present Day." Diplomas were delivered to a class of thirty-seven by Dr. Christopher Tompkins, Dean of the College.——The University College of Medicine, Richmond, held its annual commencement exercises, May 17. The annual address was delivered by Dr. Stuart McGuire, Dean of the Faculty and diplomas were conferred on a class of twenty-two. Major James C. Hemphill, editor of the *Times-Despatch*, delivered the doctorate address.

GENERAL NEWS AND COMMENT

Section Officers.—The new officers of the sections of the Americal Medical Association for 1910-1911 are as follows:

PRACTICE OF MEDICINE—Chairman, Allen Arthur Jones, Buffalo; Vice-Chairman, Charles L. Greene, St. Paul; Secretary, Wilder Tileston, New Haven; Delegate, J. A. Capps, Chicago; Alternate, Alexander Lambert, New York; Orator, C. F. Hoover, Cleveland, Ohio.

OBSTETRICS AND DISEASES OF WOMEN—Chairman, Horace G. Wetherill, Denver; Vice-Chairman, Fred J. Taussig, St. Louis; Secretary, C. Jeff Miller, New Orleans; Delegate, Arthur E. Benjamin, Minneapolis; Alternate, S. W. Bandler, New York.

SURGERY—Chairman, George W. Crile, Cleveland, Ohio; Vice-Chairman, Emmet E. Rixford, San Francisco; Secretary, John T. Bottomley, Boston; Orator, George E. Brewer, New York; Delegate, August F. Jonas, Omaha.

OPHTHALMOLOGY—Chairman, Albert E. Bulson, Jr., 219 Wayne St., Ft. Wayne, Ind.; Vice-Chairman, Edward C. Ellett, Memphis, Tenn.; Secretary, Edgar S. Thompson, New York; Delegate, John C. Bossidy, Boston.

LARYNGOLOGY AND OTOLOGY—Chairman, Roy Dunbar, Atlanta, Ga.; Vice-Chairman, W. E. Sauer, St. Louis; Secretary, George E. Shambaugh, Chicago; Delegate, H. W. Loeb, St. Louis.

NERVOUS AND MENTAL DISEASES—Chairman, W. A. Jones, Minneapolis; Vice-Chairman, Herman H. Hoppe, Cincinnati; Secretary, E. E. Southard, Boston; Delegate, Theodore Diller, Pittsburg; Alternate, J. H. McBride, Pasadena.

PREVENTIVE MEDICINE AND PUBLIC HEALTH—Chairman, W. A. Evans, Chicago; Vice-Chairman, Marshall Langton Price, Baltimore; Secretary, C. Hampton Jones, Baltimore; Delegate, J. N. Hurty, Indianapolis; Alternate, J. H. White, New Orleans; Orator, W. A. Evans, Chicago.

STOMATOLOGY—Chairman, S. L. McCurdy, Pittsburg, Pa.; Vice-Chairman, Virgil Loeb, St. Louis; Secretary, Eugene S. Talbot, Chicago; Delegate, G. V. I. Brown, Milwaukee, Alternate, M. H. Fletcher, Cincinnati.

DISEASES OF CHILDREN—Chairman, S. M. Hamill, Philadelphia; Vice-Chairman, Thomas D. Parke, Birmingham, Ala.; Secretary, L. T. Royster, Norfolk Va.; Delegate, A. C. Cotton, Chicago.

DERMATOLOGY—Chairman, James C. White, Boston; Vice-Chairman, Martin F. Engman, St. Louis; Secretary, H. R. Varney, Detroit; Delegate, J. A. Fordyce, New York.

PHARMACOLOGY AND THERAPEUTICS—Chairman, Lawrence Litchfield, Pittsburg, Pa.; Vice-Chairman, George B. Wallace, New York; Secretary, M. I. Wilbert, Washington, D. C.; Delegate, Reid Hunt, Washington, D. C.

PATHOLOGY AND PHYSIOLOGY—Chairman, Yandell Henderson, New Haven, Conn.; Secretary, Leo Loeb, Philadelphia; Delegate, Walter L. Bierring, Iowa City, Iowa; Alternate, M. J. Rosenau, Boston.

GENITO-URINARY DISEASES.—Chairman, W. T. Belfield, Chicago; Vice-Chairman, James Pederson, New York; Secretary, Hugh H. Young, Baltimore.

Academicians Meet.—The annual meeting of the American Academy of Medicine was held in St. Louis, June 4 and 6, and the following officers were elected: President, Dr. Charles S. Sheldon, Madison, Wis.; vice-presidents, Drs. Adol Alt, St. Louis; Philip Mills Jones, San Francisco; Cyrus Lee Stevens, Athens, Pa., and Henry B. Hemenway, Evanston, Ill.

Gastro-Enterologists Elect.—At the thirteenth annual meeting of the American Gastro-Enterological Association, held in St. Louis, June 6 and 7, the following officers were elected: President, Dr. Walter B. Cannon, Boston; vice-presidents, Drs. John A. Lichty, Pittsburg, and George D. Kahlo, French Lick, Ind.; secretary-treasurer, Dr. Charles D. Aaron, Detroit, and councilor, Dr. Julius Friedenwald, Baltimore.

Orthopedists Hold Meeting.—At the annual meeting of the American Orthopedic Association, held in Washington, D. C., May 3-5, the following officers were elected: President, Dr. Albert H. Freiberg, Cincinnati; vice-presidents, Drs. Aurelius R. Shands, Washington, D. C., and Robert B. Osgood, Boston; secretary, Dr. Ralph R. Fitch, Rochester, N. Y. (reelected), and treasurer, Dr. Gwilyn G. Davis, Philadelphia.

Pathology of Plague.—The Surgeon-General of the United States Public Health and Marine-Hospital Service reports that during the past year the Federal Plague Laboratory at San Francisco has furnished pathologic specimens showing the lesions of rodent plague to all medical colleges in the United States which have requested them. In this manner one hundred and four institutions have added plague material to their pathologic laboratories.

New Officers of Medical Editors' Association.—At the annual meeting of the American Medical Editors' Association, held in St. Louis, June 4 and 6, the following officers were elected: President, Dr. Joseph MacDonald, Jr., New York City; vice-presidents, Surgeon-General Walter Wyman, U. S. P. H. and M.-H. Service, Washington, D. C., and Dr. Thomas L. Stedman, New York City; secretary-treasurer, Dr. John J. Taylor, Philadelphia, and executive committee, Drs. Wallace C. Abbott, Chicago; Cyrus Lee Stevens, Athens, Pa., and Anthony G. Kreidler, Cincinnati.

Insurance Examiners Hold Meeting.—The American Association of Medical Examiners held its annual meeting in St. Louis, June 6 and 7, and adopted resolutions approving the national department of public health, and extending thanks to the members of the profession who have been pioneers in the endorsement of this proposition of having a medical scientist in charge of the new portfolio. The following officers were elected: President, Dr. Liston Homer Montgomery, Chicago; vice-presidents, Drs. W. Edward Grant, Louisville; William T. Tilly, Muskogee, Okla.; James Taggart Priestley, Des Moines, and C. T. Cutting, Seattle; secretary, Dr. Allen E. Cox, Helena, Ark., and treasurer, Dr. Thomas A. Stevens, Caney, Kan.

Change in State Board Statistics.—A graduate of George Washington University Medical Department calls our attention to the fact that in the state board statistics published in THE JOURNAL, May 21, 1910, three graduates of George Washington University Medical Department who passed the license examination in West Virginia had been reported to us as graduates of Georgetown University School of Medicine, and had, therefore, been accredited to the latter school. This correction decreases very slightly the failure percentage of the former school and increases that for the latter, but in neither case is the difference sufficient to change the classification of the college named.

Meeting of Licensing and Examining Boards.—At the annual meeting of the National Federation of State Medical Examining and Licensing Boards, held in St. Louis, June 6, Joseph C. Guensay, Chicago, was elected president; Drs. James A. Egan, Springfield, Ill., and Charles A. Tuttle, New Haven, Conn., vice-presidents; Dr. George H. Matson, Columbus, O., assistant treasurer; Dr. Darlington J. Snyder, Columbus, O., assistant secretary-treasurer; Drs. Albert H. Hamel, St. Louis, Mo., Nathaniel R. Coleman, Columbus, O., Edwin B. Harvey, Boston, James A. Duncan, Toledo, and Daniel P. Maddux, Chester, Pa., members of the executive council, and Drs. W. Fred Singer, Pueblo, Colo., and Fred C. Zapffe, Chicago, members of the newly organized examining committee.

Dr. Cushing Accepts Position at Harvard.—Dr. Harvey Cushing, head surgeon at the Johns Hopkins Hospital at Baltimore, has accepted the office of surgeon-in-chief of the proposed Peter Bent Brigham Hospital, the new teaching hospital of Harvard University Medical School. With the appointment also of Dr. Henry A. Christian, dean of the Harvard Medical School, as physician-in-chief of the hospital, the two leading places on the staff are now filled. Dr. Cushing was born in Cleveland in 1869 and comes of a distinguished medical family, both his father and his grandfather having been prominent physicians. Dr. Cushing graduated from Yale University in 1891 and from Harvard Medical School in 1895. In 1897 he received the appointment of resident surgeon at the Johns Hopkins Hospital at Baltimore, since which time he has been constantly associated with both the Johns Hopkins Medical School and Hospital, and for some years has been the associate professor of surgery in the medical school. Since 1901 Dr. Cushing has devoted his attention principally to neurologic surgery and his skill, shown in operations on tumor of the brain, as well as for injuries to the spinal cord and on various superficial nerve paralyses and neuralgias, have brought him in the front rank of American surgeons. The Peter Bent Brigham Hospital will not be completed until about 1912, which means that Dr. Cushing will not take up his residence in Boston until that time. The fund for the new hospital has been accumulating for about twenty-five years and the original bequest of $1,800,000 has grown to about $8,000,000. The hospital building will be of brick with stone trimmings and the estimated cost exceeds $1,000,000. In preparing for this hospital the trustees believed that to fulfill its highest purpose it should not only care for the sick but should serve an educational purpose to both medical students and practicing physicians. For that reason they decided to ally themselves with Harvard Medical School and the prospects are that this hospital will some time stand among the greatest hospitals in the world.

LONDON LETTER

(From Our Regular Correspondent)

London, June 3, 1910.

The Recognition of Medical Gynecology

About twenty years ago, before the modern developments of abdominal surgery, diseases of women were treated by "obstetric physicians," men who specialized on midwifery and on the minor gynecology of that time, but who never opened the abdomen. If a laparotomy was necessary the case had to be transferred to a surgeon. With the great development of operative gynecology that specialty has become a branch of surgery and is now practiced only by surgeons. Necessary and beneficial as this change is, it has one unfortunate consequence. The greater part of the work of gynecologists is devoted to the elaborate technic of abdominal surgery and in the medical schools they teach the students little else. But when the latter become general practitioners they have to treat diseases of women which generally require other than surgical treatment, about which they have learned little. They have spent their time in learning about elaborate abdominal operations which they cannot be expected to perform. Since the recent death of Dr. John W. Taylor, professor of gynecology at Queen's College, Birmingham, the successor of Lawson Tait, it has been decided to avoid this evil by rearranging the teaching of the department. It is suggested that the chair of gynecology shall be given up and that the course be called "midwifery and diseases of women," and be under the supervision of the professor of midwifery, who will deliver two-thirds of the lectures. The remaining third are to be delegated to an assistant or lecturer, who will teach the subject of diseases of women in a form suitable for the requirements of students in the after-practice of their profession. There will be no divorce between medicine and surgery, but the relative value of each will be duly estimated and explained.

Further Decline in the Birth-Rate

The summary of the vital statistics for 1909 has just been published and shows a further decline in the birth-rate. The marriage-rate was 14.6, which was 0.3 below the rate for 1908 and 1.1 below the average rate in the decade 1898-1908. The birth-rate was 25.6 per 1,000, which was 0.9 below the rate for 1908 and is the lowest on record. Compared with the average for the previous decade there was a fall of 2.2. The death rate was 14.5 per 1,000, which was 0.2 below the rate in 1908 and is the lowest on record. Compared with the average of the previous decade there was a fall of 1.6. This fall is due to diminution of the infant mortality, which has more than counterbalanced a slight increase at the other end of life. The infant mortality, measured by the proportion of deaths under the age of one year to the births, was 109 per 1,000, which was 11 below the rate for 1908, and lower than any rate on record. The reduction in the infant mortality has been mentioned in previous letters to The Journal and shown to be due to instruction of mothers and increasing care in the rearing of infants. The present reduction is all the more remarkable in that it has followed the considerable fall which has taken place since 1901. In London the marriage rate was 15.8, the lowest on record. Similarly the birth rate was 24.2, the lowest on record. This rate was 1 below that for 1908, and no less than 3.4 below the average for the previous decade. In the main the fall in the birth-rate is due to diminished fertility of married women. In 1867 the rate was 36.5, so that a fall of one-third has taken place in the last half century. For the first time since 1905 smallpox appears as a cause of death, two fatal cases having occurred.

The Output of Drugs and Chemicals in the United Kingdom

As the result of a recent law, called the Census of Production Act, reliable figures are for the first time available as to the quantity of drugs and chemicals produced in the United Kingdom. Forms were sent to all the manufacturers engaged in these industries, on which they were compelled to state the articles manufactured, the quantities manufactured, the quantities sold, the value of the articles, and the number of the work-people employed. The gross output of factories engaged in the manufacture of chemicals, drugs and perfumery in the past year is valued at $115,000,000, and the cost of the materials used at $66,000,000. The number of persons employed is 51,088. The following are some of the most interesting items: Drugs and galenical preparations, $12,000,000; fine pharmaceutical chemicals (alkaloids, chloroform, ether, etc.), $8,000,000; "patent medicines," *i. e.*, nostrums, $11,000,000; prepared foods for infants and invalids, $2,800,000; druggists' sundries, $6,400,000; essential oils, $455,000; perfumed spirits, $1,500,000.

PARIS LETTER

(From Our Regular Correspondent)

Paris, May 27, 1910.

Serious Disturbances at the Concours d'Agrégation

The tumultuous incidents will be recalled following which the *concours d'agrégation*, opened in December, 1908, was adjourned (The Journal, Jan. 16, 1909, lii, 223). Since then no new *agrégés* have been recruited. The government at last decided to announce a new *concours*. In the first session, which took place May 23, and which was to have been entirely devoted to calling the roll of the candidates, great violence broke out. When the members of the jury, preceded by the president, Dr. Landouzy, entered the great amphitheater, they were greeted by an explosion of cries and whistles. The noise was so great that Dr. Landouzy, after having tried in vain to speak a few words, was obliged to name the candidates by writing their names on the blackboards. Among the candidates were some who had entered only to disorganize the *concours*. They did not confine themelves to tumultuous shouts at the jury, but threw at them eggs and tomatoes.

The second day was marked by still greater violence. The college of medicine was occupied by police which tended to augment the disturbance among the candidates. A police officer arrested a rioter who had just thrown an egg at members of the jury; this was the signal for a regular riot between the police and the candidates. Several rioters were arrested. During the evening M. Briand, the premier, received a delegation of practitioners who came to request the liberation of the physicians and students arrested during the riot, and the withdrawal of the police. M. Briand replied that it appeared to him intolerable to allow the candidates to assault the members of the jury. Tomatoes, eggs and blows with canes did not constitute arguments. The premier added that if the violence continued the duty of the government would be not to refuse the police to assure order at the *concours*, and that the best way for the delegates to obtain the liberty of their comrades would be to stop the violence.

On the other hand, the group of "serious candidates" had drawn up a protest against the obstruction practiced by a small group of disturbers, against the violence to which the members of the jury have been subject, and against the interference with the rights of the candidates to compete in conformity with the laws and regulations. At present, thanks to the very energetic measures which have been taken to restore order, the *concours* has been resumed, but access to the ampitheater where the sessions are held is no longer open to the public. To assure the legal publicity of the sessions, however, at the opening of the doors, besides the candidates, the twenty persons who first present themselves are allowed to enter and the numerous seats left are occupied by municipal guards and the police.

Election of Professor Gaucher to the Academy of Medicine

In its session on May 25, the Académie de Médecine elected a member in the section of medical pathology to replace Professor Brissaud, who died last December. The academy elected Professor Gaucher, who is the successor of Professor Fournier in the chair of syphilitic and cutaneous diseases at the Paris College of Medicine.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, May 26, 1910.

Antituberculosis Conference

At the meeting of the German central committee for the campaign against tuberculosis referred to in my previous letter, Professor Nietner presented the business report. According to this about $40,000 (167,000 marks) was expended by the central committee during the last year for the establishment of sanatoria and other tuberculosis institutions. There are now available 99 public sanatoria with over 11,000 beds for adult tuberculous patients, in addition to 74 private sanatoria with 1,972 beds. Children with pronounced tuberculosis may be admitted to 18 sanatoria with 810 beds, and 89 institutions with 8,000 beds are provided for scrofulous children. In addition, there are 93 forest convalescence stations and 11 forest schools; 15 convalescence homes also receive tuberculous patients, and 9 observation stations permit the selection of patients for the sanatoria. There are 325 special dispensaries and advising stations for tuberculosis in Germany. The important relation between tuberculosis and the dwelling was discussed both at the general meeting and at the directors' meeting of the German central committee. According to Professor Römer of Marburg the chief cause for the spread of human tuberculosis is man himself. Almost every human being passes out of childhood already subject to tuberculous infection. In 90 per cent. of tuberculous individuals it is demonstrable that infection with tubercle bacilli occurred in childhood. The origin of tuberculous consumption in adults is to be attributed to a severe reinfection with tuberculosis from some tuberculous focus already present in the organism. The severe infections of children which result in consumption take place principally in the dwelling and within the family. The protection of children is therefore the most important problem in the prophylaxis of consumption.

Gretsel of Darmstadt, national housing inspector, treated this question from the practical standpoint, emphasizing that the common occupancy of small rooms by many individuals contributes very largely to the spread of tuberculosis. In Berlin, half of all the dwellings, namely, 197,000 (in which about half of the entire population live) consist of only a sitting room and kitchen. Thirty-three thousand apartments have only one room that can be warmed, 2,400 have no room that can be warmed, and 4,086 apartments consist exclusively of a kitchen in which sometimes as many as twelve persons live. In other large cities and in the country the conditions are quite as bad. For this reason, in addition to securing normal housing conditions, the provision of cheap, good and sanitary apartments for the less well-to-do classes in both city and country is urgently needed. The tuberculous patient ought to have his own room or at least a bed to himself, and in case of moving or death thorough disinfection should be done and, in case of need, beds should be provided. The sanitary renovation of dwellings must be undertaken at public cost, if the occupants of the house have not the necessary means. Compulsory notification of tuberculous cases must be introduced. A housing reform for the entire German empire must be carried out by legislative means. According to the statements of Professor Kirchner there exists so far no requirement to disinfect the dwelling on occasion of change of residence of tuberculous patients, or illness of members of the family from tuberculosis. There does not seem to be much prospect of legislative action to remedy this deficiency. At the suggestion of the minister of education, many communities in the last two years have indicated their readiness to undertake disinfection at public expense. The essential thing is the education of the population in cleanliness and hygiene by public instruction. Healthy children should be removed from families where disease is present and placed in healthy families to be brought up. Kirchner does not agree with Professor Römer that tuberculosis is almost exclusively acquired, nor that scarcely any human being is free from tuberculosis. According to his opinion, only those who are in the environment of tuberculous patients are endangered. Professor Petrouschky of Danzig is like Römer of the opinion that tuberculosis is acquired in childhood as a rule. Gottstein of Charlottenburg called attention to the appearance of tuberculosis in groups in various localities of the city in which the density of the population plays a prominent rôle.

The president of the imperial health office, Dr. Bumm, discussed the question whether it is necessary to obtain the permission of the patient or, in case of children, the permission of the parents before making the tuberculin skin test of von Pirquet. His conclusions were in the affirmative on the ground that otherwise physicians might be involved in litigation. In the discussion this opinion was concurred in by most of the speakers. Very favorable experiences in regard to the value of the von Pirquet test in the campaign against tuberculosis in schools were reported. One speaker urged compulsory vaccination of all school children. Experience shows that patients discharged from sanatoria find difficulty in obtaining new employment, and there was considerable discussion on measures for removing this difficulty. A combination of intelligence offices, the establishment of workshops and agricultural colonies, enlightenment of employers and similar methods were recommended. The relations of glass grinding and metal polishing and basket making to the spread of pulmonary tuberculosis were discussed by Professor Nietner, the general secretary. On account of the possibility of mechanical injury of the respiratory mucous membrane by sharp angles and points, stone dust, metal and glass dust are among the most dangerous forms. The harder the material under manipulation, the more dangerous must be the dust. As in grinding glass the work is done without exception with wet material, the development of dust is prevented and tuberculosis is not frequent among these workers. Tuberculosis is also rare among metal grinders because the workshops are adapted to modern hygienic requirements. The frequent occurrence of tuberculosis among basket workers does not depend on the trade *per se* but is to be attributed to the bad social condition of these workmen.

Pharmacology

SARTOLIN

Another Consumption "Cure"

When an American quack or nostrum-vender has milked his gullible native clientèle dry he often transfers his field of operations to Europe where he goes through the same process. In a like manner when a nostrum has worn out its welcome in Europe its astute exploiter casts his lines in American waters in hope of relieving the credulous sick of their dollars.

Sartolin is a "consumptive cure" which had its origin several years ago in Germany, its "inventor" being one Robert Schneider of Berlin. Apparently it did not take very long for this nostrum to be discredited in the land of its birth, and then advertisements began to appear in the British newspapers extolling the wonderful virtues of sartolin and detailing its "cures." Still more recently the newspapers in this country recorded the fact that "Dr." Robert Schneider of Berlin had arrived in the United States and was on his way to Chicago where he "would demonstrate his method of curing consumption." Now we find that the "U. S. Head Office & Depot" of the Sartolin Company is located in Chicago.

According to the booklet put out by the Chicago concern, Sartolin is "the newly discovered treatment for consumption and kindred diseases" and has been patented in the United States. Further we learn that the "treatment" consists of vaporizing the mixture which constitutes sartolin, and inhaling the fumes. According to the patent specifications sartolin seems to be composed of:

Powdered eucalyptus leaves	7.5
Oil of eucalyptus	4.5
Flowers of sulphur	63.0
Powdered wood charcoal	25.0

A small amount of this mixture is placed on a slab under which an alcohol lamp is burning. The whole thing is supposed to be operated in a room that is tightly closed and in which the tuberculous patient is required to stay. As the booklet of directions puts it: "The fumes are breathed in a closed bed-room during the night ...." In the advertising matter the open-air treatment is belittled and serum therapy designated as valueless. The victim is urged to use the "sartolin treatment," which consists in shutting himself up for the night in a tightly-closed room to breathe the stagnant air laden with the products both of his own exhalations and of the combustion of the stinking mixture which forms the nostrum. If there are degrees of viciousness in the various fake cures for tuberculosis it would seem that sartolin surely should rank as one of the worst.

DIGEST OF COMMENTS ON THE U. S. P.

The work of the United States government in preparing for the new Pharmacopeia by issuing bulletins containing abstracts of the comments and criticisms which have been made on the eighth decennial revision was noticed in an editorial in The Journal, Nov. 27, 1909, p. 1824. The work for 1905 was embodied in Bulletin No. 49, Hyg. Lab. U. S. Public Health and Marine-Hospital Service. A similar bulletin for 1906 has since been issued and receives extremely favorable comment from a British authority, the *Pharmaceutical Journal and Pharmacist* (April 23, 1910, p. 510). Our contemporary says:

"As an example of thoroughness in the department to which it especially applies, Bull. No. 58 of the Hygienic Laboratory of the United States is probably unequaled anywhere."

After noting the change in the status of the U. S. Pharmacopeia incident to its becoming a legal standard, the *Pharmaceutical Journal* continues:

"This status of the U. S. Pharmacopeia as the official standard for determining the purity and strength of widely used medicaments could not be maintained on better material than is to be found in this digest, for the compilation of which the pharmaceutical and chemical literature of the whole civilized world has been ransacked in a way which, one is almost compelled to think, can only be done in America. The compilers having hit on what is undoubtedly the right way to go about it, have apparently left no leaf unturned in their efforts to find material which in any way dealt critically with official articles. Commendatory notices have been studiously ignored, on the ground that the value of a compilation of comments on the officially recognized standards must lie largely in the direction of recognizing shortcomings to be corrected and errors to be eliminated. It might be expected that a volume compiled on such lines would contain all the material necessary to make the Pharmacopeia to which it refers perfect in all respects. Doubtless it does contain this material, but unfortunately ideals in most things are very apt to become modified or distorted when practical politics step in. In the present case, while bearing in mind the need of efficient and active medicaments for the conservation of the public health, the desirability of maintaining equitable standards from an economic point of view must not be lost sight of. It is a sensible view to take of the question, and our hard-headed transatlantic friends may be trusted to profit by its acceptance. All the available suggestions have been collected by the compilers without comment, and while they appreciate the fact that many of the suggestions and claims put forward are not practicable, they are none the less valuable in that they are suggestions and serve to emphasize the care that must be exercised in the final utilization of these suggestions in connection with the revision of the national standards.

"The plan of Bulletin No. 58 is quite similar to that of Bulletin No. 49 and covers the literature for the year 1906. One may appreciate the thoroughness of the search made for comments and criticisms when one notes that not only medical and pharmaceutical journals have been examined, but even an engineering journal is quoted from on page 67 (*Chem. Eng.*, Philadelphia, 1906 and 1907)."

These collections of criticisms, more than anything else, probably, should receive the credit for any improvement shown in the next revision of the book. Physicians who are interested in an advanced materia medica cannot sufficiently show their appreciation of this work. They should write to the Hygienic Laboratory for a copy of Bulletin No. 58, which will be sent on request.

Correspondence

An Improvised Pneumatic Tampon for Nosebleed

To the Editor:—I lately had a case of nasal hemorrhage that I could not control by the ordinary anterior and posterior tampons. I cut a finger from a thin rubber operating glove, inserted a catheter, pushing it up to the closed end, and tied the cut end tightly about the catheter. This was inserted into the naris and inflated by blowing into the catheter. In this case I had to tampon the posterior naris and hold the tampon tightly in place with a thread through the nostril in order to keep the glove-finger from ballooning into the pharynx. The catheter was closed by doubling and tying or by catching with a hemostat, and was held out of the way by fastening to the cheek or neck with adhesive plaster. This controlled the hemorrhage and was much more comfortable than the tampons.

A. B. Stewart, Owatonna, Minn.

Another Case of Poisoning with Mercury Bichlorid

To the Editor:—Several cases of poisoning with corrosive sublimate have been reported recently. I wish to add one more; this one being unique in the manner in which the poisoning occurred. It also shows how easy it is for children to obtain this drug.

M. R., aged 16, while visiting in a small town, became infected with pediculus *capitis*. On the advice of her grandmother she went to a druggist and purchased 10 cents worth of corrosive sublimate powder. This was mixed with an equal quantity of lard and the entire amount of the mixture was rubbed into her scalp. In a few minutes intense burning arose, and became excruciating. The girl's head was cleansed with soap and warm water, and household remedies applied to relieve the burning. In an hour intense headache, nausea, vomiting and great prostration came on. A physician was summoned and worked with the patient twelve hours before she showed any signs of improvement. At the end of three days sloughing began. Ten days after the poisoning occurred the patient returned home. I was called to see her and found no constitutional symptoms worthy of mention. The hair was dry at the extremities but matted at the roots; the scalp was a mass of crusts and ulcers, some of the crusts being 2 inches in width. A wash of 1 per cent. compound solution of cresol and green soap was ordered to be used morning and night; nitrate of silver 60 gr. to the ounce was applied to the ulcers.

At the end of four weeks the scalp was entirely healed, but there were large areas entirely denuded of hair. A tonic of cantharides and quinin was prescribed. Two months ago, or ten months after the last previous time I had seen the patient she called at my office. She stated that she had undergone scalp massage and tonic treatments during the ten months. Her hair was glossy but sparse, and there were twelve areas varying in size from a dime to a half a dollar entirely denuded of hair, the scalp here being a pearly white and glistening. The grandmother had no doubt confused red precipitate and corrosive sublimate.

Arthur D. Kurtz, M.D., Philadelphia.

The Public Service

Medical Department, U. S. Army

Changes during the week ended June 11, 1910:

Sweazey, Verge E., capt., left Hot Springs, Ark., on 4 months' leave of absence.

Gregory, J. C., capt., left Jefferson Barracks, Mo., on 2 months' leave of absence.

Pinkston, O. W., capt., left Hot Springs, Ark., en route to take station at Fort Meade, S. D.

Weed, Mark D., 1st lieut., M. R. C., reported for duty at Walter Reed General Hospital, Takoma Park, D. C.

Allen, William H., 1st lieut., M. R. C., reported for duty at Fort Slocum, N. Y.

Schlanser, A. E., 1st lieut., M. R. C., reported for duty at Walter Reed General Hospital., Takoma Park, D. C.

Bastion, J. E., 1st lieut., M. R. C., reported for duty at Walter Reed General Hospital., Takoma Park, D. C.

Bailey, Howard H., capt., detached as surgeon of the transport *Sumner* for the voyage to Buenos Aires, Argentine Republic, sailing from New York, June 14.

Love, Albert G., capt., granted leave of absence for 10 days.

Pillsbury, Henry C., 1st lieut., in addition to his other duties, is assigned to temporary charge of the Medical Supply Depot, St. Louis.

Reynolds, Charles R., major, will proceed to Gettysburg, Pa., to investigate the sanitary condition of camp site.

Lauderdale, Robert N., dental surgeon, detailed to represent the Dental Corps of the Army at the meeting of the National Dental Association, to be held in Denver, July 19 to 22.

Shugerman, Harry P., M. R. C., honorably discharged from the service of the U. S., June 7, 1910.

Foster, George B., Jr., M. R. C., ordered to Washington Barracks, D. C., for temporary duty.

Register, Edward C., M. R. C., ordered to Fort H. G. Wright, N. Y., for temporary duty.

Sheep, William L., M. R. C., ordered to Fort Myer, Va., for duty with the 3rd Field Artillery, while on detached service at Gettysburg, Pa.

Long, Charles J., dental surgeon, will proceed from Fort Adams, R. I., to Fort Banks and Rodman, Mass., to render dental service in the Artillery districts of Boston and New Bedford.

Munson, Edward L., major, detailed for duty at American Lake, Wash., camps of instruction, during August, 1910.

Cole, Blase, M. R. C., ordered to report to the Commanding Officer, 16th Infantry, to accompany Headquarters Band and 2nd and 3rd Battalions, 16th Infantry to Seattle, Wash.

Gunckel, George I., dental surgeon, ordered to Fort Screven, Ga., for a period of 3 weeks.

The following named officers of the Medical Department are detailed to accompany troops to the camps of instruction at Gettysburg, Pa.: Waterhouse, Samuel M., major; Allen, John H., major; Bailey, Howard H., capt.; Webber, Henry A., major; Davis, William R., capt.

Kouper, Conrad E., major, granted leave of absence for 20 days.

Enders, William J., M. R. C., granted leave of absence for 2 months, to take effect about July 28, 1910.

Hewitt, John M., M. R. C., relieved from duty at the Presidio of San Francisco, and assigned to duty as surgeon of the transport *Buford*, with station at San Francisco.

Medical Corps, U. S. Navy

Changes during the week ended June 11, 1910:
Stibbens, F. H., P. A. surgeon, detached from the Naval Training
Station, Newport, R. I., and ordered to the Naval Training Station,
San Francisco.
Halton, E. P., acting asst.-surgeon, detached from the Naval
Hospital, Newport, R. I., and ordered to the Naval Training Station, Newport, R. I.
Stanley, A. C., asst.-surgeon, detached from the *Virginia* and
granted sick leave for 3 months.
Ryder, C. E., P. A. surgeon, detached from instruction at
Naval Medical School, Washington, D. C., and ordered to duty at
the Naval Hospital, Naval Home, Philadelphia.
Dunn, H. A., Seaman, W., Payne, J. H., Richardson, R. R., Stepp,
J., Stuart, A., P. A. surgeons, detached from instruction at the
Naval Medical School, Washington, D. C., and ordered to examination for promotion, on completion of which to wait orders.
Tolfree, H. M., P. A. surgeon, detached from instruction at the
Naval Medical School, Washington, D. C., and ordered to wait
orders.
Hightower, C. C., and Howard, J. V., acting asst.-surgeons, appointed acting assistant-surgeons from June 4, 1910.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF INOPERABLE CANCER

To the Editor:—Please give me any information regarding late developments in the use of methylene blue or the anilin derivatives in the treatment of inoperable cancer. I have a case of recurrent pelvic cancer in a patient aged 70, operated on two and a half years ago for cancer of the rectum. What is the dosage, and does combination with nutmeg prevent vesical irritation? Does the drug tend to inhibit pain and the development of the growth? What is the present opinion as to its efficacy? Would exposure to the *x*-ray have an inhibiting effect on the growth? A. B. S.

ANSWER.—An examination of the literature shows that not much has been written recently on the use of the anilin derivatives in inoperable carcinoma, so that the procedure, which had a certain vogue a number of years ago, has probably been largely abandoned. One of the most recent articles published in THE JOURNAL concerning the use of the methylene blue in cancer is that of Dr. A. Jacobi (THE JOURNAL, Nov. 10, 1906, p. 1545). In this paper Dr. Jacobi reports having used it in at least 120 cases extending over a period of fifteen years, with good results in the way of relieving pain, retarding or diminishing the growth and size of the neoplasm and prolonging life, in many cases for a number of years beyond the probable length of life without treatment. He gave the drug in small doses, beginning with 2 grains a day, running it gradually up to 3, 4 and 6 grains a day, combining it in pill form with belladonna, which he found more effective in preventing dysuria than nutmeg, giving three-fourths of a grain in the daily dose. He also frequently used 1/40 to 1/20 grain of arsenic trioxid and also 1/10 grain of strychnin in the daily dose. Patients should be told that the urine will be blue. In a discussion of Dr. Jacobi's paper, H. R. Slack reported using it hypodermically, 1 c.c. of a 2 per cent. solution every other day, with alleged beneficial results. References to the use of this and other anilin derivatives will be found below. The *x*-ray is still used to some extent in the treatment of superficial cancer and for the prevention of recurrence after operation in surface growths. It has an analgesic effect. It is found less effective in deep-seated growths such as the one referred to.

THE UNCINARIA AND THYMOL TREATMENT

To the Editor:—1. Are hookworms visible to the naked eye? 2. Are the eggs visible to the naked eye? 3. What is the best method of administering thymol? C. W. BENSON, Bartlett, Tex.

ANSWER.—1. Hookworm comprises two species: *Ankylostoma duodenale* (the old-world species) and *Uncinaria americana* or *Necator americanus* (the new-world hookworm). *Ankylostoma duodenale* is described as follows: The length of the female is 8 to 18 mm. (⅓ to ⅔ inch); that of the male 8 to 12 mm. (⅓ to ½ inch). The head of the worm, which is curved backward, is *conical* and has a large bell-shaped mouth, surrounded by a horny capsule and possessing four hook-like teeth ventrally situated and two smaller vertical teeth on the dorsal side by which the worm fixes itself to the mucous membrane. The body is thread-like. The tail of the female ends in a point, but that of the male contains a three-fold bulbous swelling in which the intestine and vas deferens end. The hookworm is easily visible to the naked eye but a low power of the microscope is necessary to make out the details of the structure just described. *Uncinaria americana* has no hook-like teeth but has a dorsal pair of prominent semilunar plates or lips and a ventral pair of slightly developed lips of the same nature. The female varies less in length than that of *Ankylostoma duodenale*, being 9 to 11 mm. long.

2. The eggs are not visible to the naked eye but can be seen with the low power of the microscope. The eggs of *Ankylostoma duodenale* are about 0.05 mm. (1/500 inch) long and about half as broad and show segmentation in the shape of 2 or 3 furrows. The eggs of *Uncinaria americana* are somewhat larger—64 to 72 by 36 to 40 microns.

3. Thymol should be given in capsule, the crystals being first triturated with sugar of milk to prevent agglomeration, or in emulsion with acacia in 30-grain doses repeated in two hours for an adult. In administering thymol, it is essential that none of the solvents of the drug should be given either with it or immediately after. The solvents include alcohol or alcoholic drinks, ether, chloroform, glycerin and oils. In order to prevent poisoning by thymol it should be followed by a saline purge, and castor oil should not be used. For further details see THE JOURNAL, Oct. 16, 1909, p. 1307; also article by E. E. Lindeman in THE JOURNAL, May 28, 1910, p. 1765. In the search for uncinaria, if the microscope is not at hand, it is recommended by Stiles to give a small dose of thymol, followed by Rochelle salt, and to collect all the stools passed: to wash the stools several times in a bucket and to examine the sediment for worms about half an inch long, about as thick as a hairpin or hatpin and with one end curved back to form a hook.

EFFECT OF CHOCOLATE ON THE URINARY ORGANS

To the Editor:—Please give information concerning the following questions: 1. What is the explanation of irritation of the urinary organs and passages following the ingestion of chocolate and chocolate candies, usually in large amounts? 2. On what substances in the chocolate, or chemical changes induced in the digestion do the irritating qualities depend? 3. Kindly give a chemical analysis of ordinary chocolate. X. Y. Z.

ANSWER.—1. We are unable to find any statement that irritation of the urinary organs is a common result of the ingestion of chocolate or chocolate candies. If this symptom has been observed, it appears not to have been made the subject of pharmacologic investigation.

2. The principal constituents of the cacao bean are fat (oleum theobromatis), theobromin, other nitrogenous substances, volatile oil, tannin and cocoa red, and gum. The fat is a non-irritating, easily digestible substance having a composition similar to other fats, with the exception that it contains a glycerid of arachidic acid. It is improbable that irritation could be produced by the fat unless indirectly by disturbing digestion in susceptible people. Theobromin (dimethylxanthin) is a base similar to caffein (trimethylxanthin) and acts as a powerful diuretic. It is converted to a large extent into purin compounds and may possibly increase the amount of uric acid in the urine. The other nitrogenous substances are mostly insoluble and indigestible and have no constitutional effect. Nothing appears to be known about the action of the tannin and cocoa red or the gum. It is supposed that the aroma of cocoa depends on a volatile oil, but nothing is known regarding its pharmacologic action so far as we can learn.

3. Ordinary chocolate consists of the roasted and ground cacao beans, from which a portion of the fat has been removed and the residue pressed into cakes, either with or without the addition of sugar. In consequence of the varying methods of manufacture, it is not practicable to give an exact analysis of ordinary chocolate. The following is an analysis of the Caracas cocoa nibs: Moisture, 7.77; nitrogenous substances, including theobromin, 14.13; theobromin, 1.48; fat, 45.54; starch, 19.40; cellulose, 6.19; ash, 4.91; sand, 2.06 (Weighman).

Marriages

BERT L. WARE, M.D., Fort Smith, Ark., to Miss Bessie Chandler, of Greenwood, Ark., June 5.

GEORGE S. FULTZ, M.D., Broadway, Va., to Miss Alma K. McDowell, at Broadway, June 8.

HOMER B. CATRON, M.D., Hanaford, Ill., to Miss Edna Earle Price, of Belle Rive, Ill., June 1.

DONALD CHURCH BALFOUR, M.D., to Miss Carrie Louise Mayo, both of Rochester, Minn., May 28.

BERNARD J. LACHNER, M.D., Rock Island, Ill., to Miss Anna Elizabeth Kelley, of Philadelphia, June 1.

CHARLES E. HOWARD, M.D., Cogswell, N. D., to Miss Florence E. Latourell, of Mankato, Minn., recently.

JOHN ROBERTS CAULK, M.D., Easton, Md., to Miss Bessie Jenifer Harrison, at Towson, Md., June 1.

JOHN P. FLETCHER, M.D., U. S. Army, to Miss Jeannette Mattfeldt, at Mount Washington, Md., June 1.

ROYDEN WINTHROP DAVISON, M.D., Trenton, N. J., to Miss Inez May Gruber, of New Haven, Conn., June 1.

JOHN JAMES KENNEDY, M.D., Mill Creek, W. Va., to Miss Mary Louise Miller, at Cumberland, Md., June 1.

ROBINETTE BURNS HAYES, M.D., Fayetteville, N. C., to Miss Minnie Bond Anderson, at Baltimore, June 1.

LOUIS WARDLAW HASKELL, JR., M.D., Memphis, Tenn., to Miss Robin Hamilton, at Mount Sterling, Ky., June 1.

HERMAN A. BECK, M.D., Lebanon, Ind., to Miss Nellie Goodnight, of Kempton, Ind., near Elizaville, Ind., recently.

Deaths

Henry Granger Piffard, M.D. College of Physicians and Surgeons, New York City, 1864; a member of the American Medical Association, New York Academy of Medicine and American Dermatological Association; who served in 1862 with the United States Sanitary Commission, and in 1867 and 1868 as the surgeon of the Seventh Regiment N. G. S. N. Y.; president of the New York Dermatological Society in 1876; since 1869, surgeon to the New York Dispensary for Diseases of the Skin; and since 1871, surgeon to the Charity Hospital; in 1873 and 1874, lecturer on urinary analysis in the University of the State of New York, and since 1874, professor and emeritus professor of dermatology in that institution; consulting surgeon to the City Hospital; author of several standard books on diseases of the skin and genitourinary system; died at his home in New York City, June 8, from pneumonia, aged 67.

Simon Leopold Elsner, M.D. College of Physicians and Surgeons, New York City, 1887; a member of the American Medical Association; examiner for the National Jewish Hospital for Consumptives, Denver; formerly chairman of the gynecological section of the Rochester (N. Y.) Academy of Medicine; assistant physician to the Rochester City Hospital; died suddenly in Rochester, June 5, from angina pectoris, aged 43.

Samuel L. Dutton, M.D. Harvard Medical School, Boston, 1860; a member of the Massachusetts Medical Society; assistant surgeon of the First Massachusetts Volunteer Heavy Artillery and later surgeon of the Fortieth Massachusetts Volunteer Infantry, and surgeon-in-chief of the Third Brigade First Division Eighteenth Army Corps during the Civil War; for many years pension examining surgeon for Boston and vicinity; died at his home in Chelmsford, May 27, aged 74.

Oscar Fordyce, M.D. College of Physicians and Surgeons, Chicago, 1885; a member of the American Medical Association; president of the Guthrie County (Iowa) Medical Society, and a member of the Iowa State Association of Railway Surgeons; local surgeon for the Rock Island System at Guthrie Center, and commissioner of insanity for Guthrie county; chief surgeon of the Fordyce Hospital; was instantly killed in an automobile accident, near Guthrie Center, June 5, aged 49.

John Stewart Kulp, M.D. University of Pennsylvania, Philadelphia, 1889; who entered the United States Army as assistant surgeon in 1893, was made captain and assistant surgeon in 1898, major in the medical corps in 1906, and was retired, Dec. 4, 1908, on account of disability in line of duty and moved to Seattle and was appointed surgeon of the National Guard of Washington in 1909; died in a hospital in Seattle, June 3, aged 44.

William C. Chapman, M.D. Miami Medical College, Cincinnati, 1873; a member of the American Medical Association; for several years president of the Toledo Federation of Charities; a member of the medical staff of St. Vincent Hospital, and for several terms a member of the board of health of Toledo; died at his home, May 29, from nephritis, aged 69.

Camillus Bush, M.D. Johns Hopkins University, Baltimore, 1902; of San Francisco; a member of the American Medical Association; assistant in surgery in the University of California, and visiting surgeon to St. Helena Sanitarium; died in the Adler Sanatorium, Woodland, Cal., May 28, from typhoid fever, aged 32.

Henry S. Wishart, M.D. University of Pennsylvania, Philadelphia, 1864; a veteran of the Civil War, and representative from Fulton county in the legislature in 1875 and 1876; for many years a practitioner of McConnellsburg, Pa.; died at the home of his daughter in Johnstown, June 2, from cerebral hemorrhage, aged 78.

John Edward Groves, M.D. Bennett Medical College, Chicago, 1887; a member of the *Effingham County* (Ill.) Pension Board; died at his home in Altamount, May 17, from perforation of the bowels and stomach, due to an abscess of the gall-bladder, for which two operations had been performed, aged 45.

Henry Napoleon Austin, M.D. College of Physicians and Surgeons, New York City, 1865; for many years a practitioner of south Arkansas, near Pine Bluff, and one of the founders of the Austin Company at Dumas, died in Asheville, N. C., April 20, from carcinoma of the neck, aged 72.

George K. Meschter, M.D. University of Pennsylvania, Philadelphia, 1867; vice-president of the Perkiomen Seminary, Pennsburg; a leader of the Schwenkenfelder Church; died at his home in Centre Point, Worcester, Pa., June 4, from cerebral hemorrhage, aged 70.

Stiles Kennedy, M.D., University of Pennsylvania, Philadelphia, 1858; a member of the Michigan State Medical Society; and for more than half a century a practitioner of St. Louis, Mich.; died at his home, May 27, from cerebral hemorrhage, aged 72.

Murray Sims Hitchcock, M.D. Louisville Medical College, 1893; a member of the American Medical Association; formerly surgeon for the Alabama Consolidated Coal and Iron Company at Brookwood, Ala.; died at his home in Birmingham, May 27, aged 43.

Edwin H. Knowles, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1879; a veteran of the Civil War; member of the board of health of North Stonington; in 1889 a member of the state senate; died at his home, May 30, from nephritis, aged 67.

William H. Gray (license, examination, Ind.); of Michigan City; a veteran of the Civil War; who was adjudged insane, May 18, and committed to the Northern Indiana Hospital for Insane, Logansport; died in that institution, June 2, aged 71.

Rio Delos Barber, M.D. Harvard Medical School, Boston, 1866; a veteran of the Civil War, and for twenty years a practitioner of Corona, Cal.; died at his home in that place, May 26, from heart disease, aged 71.

Frederick Selnow, M.D. University of Goettingen, Germany, 1862; for more than 40 years a practitioner of Hudson county, N. J.; died at his home in lower Jersey City, May 20, from myocarditis and nephritis, aged 75.

Thomas W. E. Winders, M.D. Fort Worth (Texas) University, 1906; a member of the Tombstone Medical Society; died at his home in Tombstone, Ariz., Aug. 7, 1909, from peripheral neuritis, aged 24.

Reuben K. Dawson, M.D. University of Nashville, 1858; for many years a practitioner and clergyman of Maury county, Tenn.; died at his home in Knob Creek, June 3, from heart disease, aged 78.

William Krause, M.D. Jefferson Medical College, 1884; for a long time a sufferer from an incurable disease; died at his home in Philadelphia, June 3, from asphyxiation by illuminating gas, aged 63.

Beverly Allen Henry, M.D. Jefferson Medical College, 1852; a practitioner of Elberton, Ga., for many years; died at his home, "Henry Place," Elberton, April 12, from senile debility, aged 81.

William H. Dunn, M.D. Medical College of Ohio, Cincinnati, 1874; of Gaston, Ind.; a member of the Delaware County Medical Society; died in Indianapolis, May 30, from heart disease, aged 63.

James T. Prevatt, M.D. George Washington University, Washington, D. C., 1905; a member of the Medical Association of Georgia; died at his home in Monticello, May 27, aged 38.

George Almarian Dean, M.D. Hahnemann Medical College, Chicago, 1878; for 25 years a practitioner of Kansas City; died at his home, June 1, from cerebral hemorrhage, aged 64.

Hugh C. Calloway, M.D. Beaumont Hospital Medical College, St. Louis, 1890; a member of the Wyoming State Medical Society; died at his home in Lander, May 23.

George Waldron Bartlett, M.D. New York Homeopathic Medical College, 1895; died at his home in Bath Beach, Brooklyn, N. Y., June 5, from heart disease, aged 57.

Alfred R. Ligon, M.D. Southwestern University Medical College, Dallas, 1904; died at his home in Henderson Cross Roads, Tenn., May 31, from pellagra.

Silas Warrick Hall, M.D. Starling Medical College, Columbus, Ohio, 1849; died at his home in Weston, W. Va., May 18, from malignant disease, aged 85.

Charles Rowley Enos, M.D. Homeopathic Medical College, St. Louis, 1874; died at his home in Jerseyville, Ill., May 12, from senile pneumonia, aged 95.

John Thomas Richter, M.D. Kentucky University, Louisville, 1904; of Louisville; was struck by a street car, June 1, and instantly killed, aged 30.

R. T. Long (license, Tenn., 1889); for many years a practitioner of Columbia, Tenn.; died at his home, May 29, from cardiac asthma, aged 70.

Thomas F. Joyce, M.D. New York Homeopathic Medical College, New York City, 1859; died at his home in Brooklyn, Dec. 16, 1909, aged 71.

W. A. Boyd, M.D. University of Louisville, 1853; died at the home of his daughter in Mayfield, Ky., May 31, from cerebral hemorrhage, aged 78.

PROCEEDINGS OF THE ST. LOUIS SESSION

MINUTES OF THE SIXTY-FIRST ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ST. LOUIS, MO., JUNE 6-10, 1910

Third Meeting — Tuesday Afternoon, June 7

The House of Delegates met at 2 p. m., and was called to order by President Welch. The Secretary called the roll.

Dr. H. Bert Ellis, Chairman, presented a supplementary report of the Committee on Credentials.

The minutes of the previous meeting were approved.

Report of Committee on Scientific Exhibit

Dr. Frank B. Wynn, Indiana, Director, read the report of the Committee on Scientific Exhibit, as follows:

To the Members of the House of Delegates:

The Scientific Exhibit of the St. Louis session will compare favorably with previous exhibitions, especially in the variety of material presented. It has been the policy of the committee from year to year to seek to widen the range of instructive exhibits beyond the museum type, so as to include all forms of medical activity. The present exhibit shows an encouraging response in this direction. It will give emphasis and illumination to the following subjects:

1. The clinical application of research work.
2. The practical value of thorough scientific work, whether in the laboratory or the hospital.
3. The methods of newer medical teaching.
4. The progress of clinical work in hospitals and dispensaries.
5. Newer methods in dealing with the tuberculosis and other sanitary and hygienic problems.
6. The rôle of parks and playgrounds in conserving the public health and comfort.
7. The advantages of competent food and dairy inspection.
8. The desirability of local medical societies giving more attention to medical history.

A booklet issued at the time of registration gives details as to institutions and exhibitors. Thirty-three institutions are represented in the Exhibit, and no less than fifty members of the Association have aided in its preparation or presentation. The local profession have abundantly atoned for any past delinquency in participation by a most generous patronage of the present Exhibit under the efficient direction of Dr. F. J. Lutz.

When it is recalled that the labor of preparing this Exhibit is largely gratuitous, the services of the men become an eloquent testimonial to their unselfish devotion to the higher ideals of medicine. Theirs is a labor of love, and their reward the consciousness of service to others, which, after all, is the true foundation of happiness.

Following the plan of a year ago, certificates of honor will be given to a limited number of exhibitors. Gold medals will be awarded (a) for the best research exhibit relating to some phase of pathology or internal medicine, and (b) for the best research exhibit bearing on clinical surgery. A committee on awards (of three members) should be appointed by the President at once.

It is recommended that $500 be appropriated to meet the ordinary expenses for the ensuing year, and $300 for medals, certificates of honor and small cash grants to encourage exhibitors who have made heavy personal outlay, especially in investigation work.

The Scientific Exhibit has abundantly proved its usefulness. The benefits are to be reckoned not merely by the practical lessons taught the visiting members of the Association at each annual session. An educating influence still more potent has been stimulated, through the friendly rivalry of institutions which have participated. The practical effect has been the growth of museums in colleges and hospitals, and the advancement of the standards in medical teaching. Traceable, likewise, to the Association's efforts are the exhibits now generally in vogue for the education of the public on the various sanitary and hygienic problems.

What is to be the future of the Scientific Exhibit? Have the limits of its usefulness been attained? Must we continue in the path now well beaten, or are there other fields to explore and develop?

In answering these questions it may be well to call attention to a rapidly growing sentiment in the Association that the organization should take a hand in a large way in spreading knowledge among the people concerning the problems of hygiene, sanitary science and all matters relating to the public health and comfort. While the campaign under the efficient direction of Dr. McCormack had for its primary object medical organization, he sought to blaze the way for judicious medical instruction of the public. This same sentiment was voiced at the last session of the House of Delegates by the passage of a resolution calling on county medical societies to devote at least one annual meeting to a publicity program.

There are so many ways in which well organized and well directed medical effort would aid the public weal that the question may well be asked: *What is the Best Thing to Do?*

Objection is raised against the Association entering on a campaign of publicity, because it is claimed that the field is already occupied by the American Public Health Association, the National Association for the Study and Prevention of Tuberculosis, Boards of Public Health, etc. The same reasoning would have prevented the Association from elevating the standard of medical education or attempting the eradication of the proprietary medicine evil.

Again, it is asserted that health boards would resent activity of the Association in this field as an intrusion. On the contrary, it is just such national, cooperative support from nonpolitical sources that health boards everywhere feel the need of. On every hand they are hampered in the prosecution of public health work; at one time by a suspicious and uneducated public sentiment; at another time by narrow-minded and pernicious public officials, more concerned in guarding the interest of corn, hogs and corporations than in the protection of the people's health; or, more frequently still, public health officials are held fast in the mire of politics.

No one will contend that the Association should undertake the details of police surveillance in public health matters. Its functions should be educational and advisory. It is entirely practicable for the organization to inaugurate and exert a powerful moral and educational force throughout the country which will prepare the soil for the growth of public health work. It should seek in every way possible to divorce this type of public service from politics. It may furthermore undertake very properly the standardization of public health methods.

Many health boards, state and local, well officered and with ample funds, are doing magnificent work. Many others, because of local conditions, inadequate financial aid or bungling methods, are bringing discredit on preventive medicine in the public mind.

Granting that the Association should undertake a campaign of publicity: *What Is the Best Method to Pursue?*

Public lectures, accompanied by stereopticon views and exhibits, constitute the most popular method at the present time. Forensic presentations, when well conducted, are most valuable and should be continued and extended. Such efforts, however, are apt to be spasmodic—occurring at long intervals. Towns, villages and the rural districts do not enjoy their benefits. There is wanting, also, that continuity of educational effort which counts.

Forensic presentations are open to the further objection that they may not be judiciously conducted. Through inexperience or lack of adaptation to the work, bungling may result. Recently, in a college town, a course of talks to students on sexual hygiene and the social evil was presented with so little judgment and tact that it brought the ridicule and condemnation of the student body, causing abandonment of the movement by faculty action. Another, and not a small objection to local forensic presentations on public health matters, is that many people look on them as a scheme of doctors for personal ends; and the prominence of a few medical men in the work often arouses jealousy and unworthy criticism from rival members of the profession.

The practical utility of the public health exhibit as a means of instructing people has been abundantly demonstrated. The information they receive in this manner is more likely to be carefully weighed. The knowledge people gain through the eye from pictures, charts, models, etc., makes more lasting impression than the spoken word. The impersonality of the exhibit is another factor to commend it. Local jealousies and criticisms are not so apt to be aroused.

Your Committee on Scientific Exhibit has for several years given careful study to the matter of public health exhibits as ordinarily conducted. They are generally heterogenous and wanting in systematic arrangement. Often the data they contain are unwarrantably sensational, terrifying or misleading to the public. They are cumbersome in size. Their initial cost is great, and their maintenance and presentation necessitate a large expenditure. They are only practicable, therefore, for the health boards of states and large cities. Only at long intervals are they available for county seats. Villages and the country districts do not receive their benefits. These exhibits are of the traveling kind; their effect, like that of the traveling revivalist, may once in a long period stir up a little hygienic or sanitary fervor, but in a short time after the "big meeting" is over the people become backsliders. Let us make hygienic and sanitary reform a religion of daily life.

Your committee is under the conviction that the exhibit offers the most practical means of bringing this to pass. It lies within the power of this Association to develop cheap, compact, and yet complete exhibits relating to all the problems of the public health and comfort. It would be possible in this way to standardize to a large extent public health methods throughout the country. The wise and judicious hand of the Association would guard against erraticism in the field of preventive medicine, and seek on every hand to cooperate with and aid existing forces working for the public health and comfort.

Your committee is impressed with the feasibility of such a publicity campaign by means of exhibits. We would therefore ask for the appointment of a representative special committee to meet in conference with the Committee on Scientific Exhibit for more detailed consideration of the plan, to be reported back to this body.

Respectfully submitted,
FRANK B. WYNN, Director.

The President stated that unless there was objection, the report of the Committee on Scientific Exhibit would be referred to the Board of Trustees, and as there was none the report was so referred.

Report of the Committee on Scientific Research

In the absence of Dr. Alfred Stengel, Pennsylvania, Chairman, the General Secretary read the report, as follows:

To the Members of the House of Delegates of the American Medical Association:

Your Committee on Scientific Research would report that it has made for the current year three grants which become effective, the amount being $200 for each grant.

The first of these is to Dr. R. M. Pearce, of New York, for the following pieces of work which will be presented at the meeting of this year:

1. Homer F. Swift. The effect of Treatment on the Wassermann Reaction.
2. Thomas MacRae, A. B. Eisenbrey, and Homer F. Swift. The Use of Pure Lipoids and Alcoholic Extracts with Active and Inactive Serum in the Complement Fixation Tests for Syphilis.
3. Homer F. Swift and William C. Thro. A Study for Streptococci with the Complement Fixation and Coglutination Reactions.

These three studies were made in the laboratory of Dr. Pearce and under his direction.

The second grant is to Dr. Gerald B. Webb, of Colorado Springs, for a report on "Production of Immunity by Inoculation of Living Bacteria."

The third to Dr. E. C. Rosenow on "Studies on the Pneumococcus."

Several other applications were made and grants would have been made but for delay or failure of applicants to complete their work.

The Committee has exercised a great deal of discretion in making grants, and requests that the amount allowed at last year's meeting be not reduced, as the pending applications which have not become effective this year will be repeated for the following year.

ALFRED STENGEL, Chairman.

On motion of Dr. Alexander R. Craig, Pennsylvania, the report was referred to the Board of Trustees.

Report of Committee on Organization of Council on Public Health, Publicity and Legislation

In the absence of Dr. Charles A. L. Reed, Ohio, Chairman, the General Secretary read the report, as follows:

To the Members of the House of Delegates of the American Medical Association:

Your committee presents the following amendments to the constitution and by-laws:

Amend Section 3 and Chapter 10, page 19 of the by-laws, to read as follows:

(a) Judicial Council.
(b) Committee on Transportation and Place of Session.
(c) Council on Medical Education.
(d) Council on Legislation, Health and Publicity.

Strike out Sections 5 and 8 of Chapter 10 and substitute for Section 5 the following:

There shall be a Council on Legislation, Health and Publicity to consist of five members, to be elected by the House of Delegates, on nomination by the President. Those first appointed shall serve one for one year, one for two years, one for three years, one for four years and one for five years. The respective terms of service shall be determined by lot and thereafter one member shall be elected annually, on nomination by the President. The President shall have power to fill by appointment all vacancies arising from any cause during intervals. The Council shall organize and shall elect a Chairman from its number. The Board of Trustees shall appoint a Secretary on nomination by the Council, and shall fix his salary.

The Council shall adopt such rules and regulations for the government of its actions as it may deem expedient. It shall expend money or contract financial obligations only as shall be authorized in writing by the Board of Trustees.

The work of the Council shall embrace the following subjects:
(a) Legislation.
(b) Organization.
(c) Publicity.
(d) Defense of Medical Research.
(e) Health.

It may appoint committees to carry on the respective purposes of the Council.

It shall make an annual report of its work to the House of Delegates.

The office of the Council shall be at the headquarters of the Association.

Respectfully submitted,
CHARLES A. L. REED, Chairman.

On motion, the amendments were referred to the Reference Committee on Constitution and By-Laws.

Report of Reference Committee on Sections and Section Work

The report was read by the Chairman, Dr. John E. Weeks, as follows:

To the Members of the House of Delegates of the American Medical Association:

At a meeting of the Reference Committee on Sections and Section Work, at which all of the members were present, proposals to establish a "Section on Urology and Venereal Diseases," a "Section on Physical Forces in Medicine" and a "Section on Hospitals," referred to this committee by your body, were considered. Arguments in favor of these proposals were listened to and the data submitted. It was unanimously agreed to submit the following recommendations:

GENITO-URINARY SECTION FORMED

1. That a section entitled "Section on Genito-Urinary Diseases" be authorized and established at this session. It is further recommended that the following named gentlemen be appointed officers of this section to serve during the first year of its activities, and that these officers be empowered to appoint an Executive Committee of three—one member to serve one year, one to serve two years, and one to serve three years, the subsequent election of officers and the constitution of the Executive Committee being provided for in the By-Laws of this Association.

Officers: Dr. W. T. Belfield, Chicago, Chairman; Dr. James Pederson, New York, Vice-Chairman; Dr. Hugh Young, Baltimore, Secretary.

2. In regard to the proposal to establish a section to be known as the "Section on Physical Forces in Medicine," your committee is unanimously of the opinion that the time is not yet opportune for the establishment of such a section.

3. In regard to the proposal to establish a section to be known as the "Section on Hospitals," your committee finds

that the subject is not yet sufficiently advanced to make it evident that there is sufficient demand for the creation of such a section. Your committee, therefore, respectfully recommends that this proposal be referred back to the proposers for subsequent presentation if they so desire, when, in their opinion, sufficient support has been obtained to warrant favorable action by the committee to which it may be referred.

John E. Weeks, Chairman.
E. C. Hay, Secretary.
C. J. Smith.
Alfred D. Sawyer.
Orland J. Brown.

It was moved and seconded that the report be adopted. Carried.

Report of the Reference Committee on Medical Education

Dr. Hubert Work, Colorado, Chairman, presented the report of the Reference Committee on Medical Education, as follows:

To the Members of the House of Delegates of the American Medical Association:

Your committee believes that we are, at the present moment, at a very important stage in the efforts of the American Medical Association to benefit the community by raising the standards of medical education. For this reason the Committee has given the report of the Council on Medical Education careful and critical study.

We wish to congratulate the Council on the excellent work it has done, and on the great progress in medical education since it began its work, six years ago. This is shown not only in the raising of standards of admission, but in the more systematic and better arrangement of the curriculum, and in improvement in the personnel and methods of teaching, which now approach more nearly to university standards.

When the Council began this work there were 168 medical schools in the United States. Some of the poorest schools have been forced to discontinue. A number have disappeared through the amalgamation of schools, thus making stronger and better schools. The number has now been reduced to 133.

Much of this improvement is due to the methods by which the work of the Council is carried out. With a paid Secretary, devoting his whole time to this work, the Council has been able to establish a bureau of statistics and information on medical education, which is invaluable in the study of these problems.

Furthermore, it has been enabled to undertake a work that was much needed, yet for which there seemed to be no established official agency—namely, the investigation of the actual standing and condition of the various medical schools of the country. This investigation has covered several years. We believe it has been done conscientiously and with thoroughness. The standing of all schools has been made on a uniform basis of marking that is broad and fair. Whatever questions there might be as to the absolute value of the rating given a school, there can be no question that the rating fairly expresses the relative standing of the schools.

After investigation, the Reference Committee is impressed by the leniency with which these ratings have been made. Consequently, we would urge the schools in Class A (rated over 70 per cent.) not to feel that they have reached perfection because they are designated "first class." Class A contains 70 schools.

The schools in Class B were rated at 50 to 70 per cent. They are unsatisfactory, in certain particulars, but capable of improvement to a satisfactory basis. To all these schools information has been sent, showing in what lines improvement should take place. There are 29 schools in this class.

Class C comprises the schools falling below a rating of 50 per cent. Some of these schools are regarded as hopeless; others can be made satisfactory only by a thorough reorganization along more advanced lines. The Council will gladly furnish information to these schools as to their short-comings, if they desire it. Twenty-seven schools belong to Class C.

The schools for colored students have been classified on a still more lenient basis. This is justified, not on the ground of any racial difference, but on account of peculiar educational conditions.

TO PUBLISH RATINGS OF SCHOOLS

The Council believes that the time has come when the best interests of medical education demand that this rating of schools should be made public. In this opinion the Reference Committee concurs. It seems to be a disagreeable but necessary duty.

We would, therefore, recommend that the House of Delegates authorize the publication of the rating of the schools. We believe that the Association should assume this responsibility.

We would recommend, secondly, that the Council be requested to continue its investigations along these lines in some conservative way. We shall thus secure a healthy advance on the part of the worthy schools, yet shall not aim at impossible results.

Thirdly, we would recommend that the Council be encouraged to continue its plans for securing the cooperation of all organizations which are interested in the improvement of medical education, but we would have them continue to recognize that the American Medical Association should establish its own standards, and that these standards can be only such as the present status of education in the United States warrants.

FOR UNIFORM PRACTICE ACTS

Fourthly, we believe that the House of Delegates should urge the Council to further efforts in the direction of securing more uniform state regulation of the practice of medicine, and in securing reciprocity between states.

Finally, we would endorse a plan that the Council mentioned to your Committee for the establishment of a registry of medical students. Such a plan has been carried out by the General Medical Council of Great Britain, and it should be of great benefit. As it would involve further expense, your Committee recommends that the House of Delegates approve this plan and refer it to the Trustees for action.

Respectfully submitted,
H. D. Arnold, Massachusetts.
T. D. Tuttle, Montana.
J. A. Capps, Illinois.
James B. Bullitt, Mississippi.
Hubert Work, Colorado, Chairman.

As a supplement to its report, the Committee presented the following classification of medical colleges, furnished by the Council on Medical Education:

CLASS A.—ACCEPTABLE MEDICAL COLLEGES

1. Giving a complete four-year course:

Alabama
  University of Alabama Medical Department.
California
  Leland Standford Junior University Medical Department (Cooper Medical College).
  University of California, Medical Department, San Francisco-Los Angeles.
Colorado
  Denver and Gross College of Medicine.*
  University of Colorado, School of Medicine.*
Connecticut
  Yale Medical School.
District of Columbia
  George Washington University, Department of Medicine.
  Georgetown University, School of Medicine.
Illinois
  Northwestern University Medical School.
  Rush Medical College [illegible]go.
  College of Physicians [illegible]ago.
  Hahnemann Medical [illegible], Chicago.
Indiana
  Indiana University School of Medicine.
Iowa
  State University of Iowa, College of Medicine.
  State University of Iowa, Homeopathic College.
  Drake University, College of Medicine.
Kansas
  University of Kansas, School of Medicine.
Kentucky
  University of Louisville, Medical Department.
Louisiana
  Tulane University of Louisiana, Medical Department.
Maine
  Medical School of Maine.
Maryland
  Johns Hopkins University, Medical Department.
  University of Maryland, School of Medicine.
  College of Physicians and Surgeons, Baltimore.
  Baltimore Medical College.
Massachusetts
  Boston University, School of Medicine.
  Harvard Medical School.
  Tufts College Medical School.
Michigan
  University of Michigan, Department of Medicine and Surgery.
  University of Michigan, Homeopathic College.
  Detroit College of Medicine.
Minnesota
  University of Minnesota, College of Medicine and Surgery.

---

* These two colleges have been merged and will constitute the School of Medicine of the University of Colorado.

Missouri
St. Louis University, School of Medicine.
Washington University, Medical Department.
University Medical College, Kansas City.
Nebraska
Creighton Medical College.
University of Nebraska, College of Medicine.
New Hampshire
Dartmouth Medical School.
New York
Albany Medical College.
Columbia University, College of Physicians and Surgeons.
Cornell University Medical College.
Fordham University, School of Medicine.
Long Island College Hospital.
New York Homeopathic Medical College and Hospital.
Syracuse University, Medical Department.
University and Bellevue Hospital Medical College.
University of Buffalo, Medical Department.
Ohio
Ohio-Miami Medical College, Medical Department, University of Cincinnati.
Starling-Ohio Medical College.
Western Reserve University, Medical Department.
Oregon
University of Oregon, Medical Department.
Pennsylvania
Hahnemann Medical College and Hospital, Philadelphia.
Jefferson Medical College.
Medico-Chirurgical College of Philadelphia.
University of Pennsylvania, Medical Department.
Woman's Medical College of Pennsylvania.
University of Pittsburg, Medical Department.
Tennessee
Vanderbilt University, Medical Department.
Texas
University of Texas, Medical Department.
Vermont
University of Vermont, College of Medicine.
Virginia
Medical College of Virginia.
University College of Medicine.
University of Virginia, Department of Medicine.

2. *Giving a two-year course acceptably:*

Mississippi
University of Mississippi, Medical Department.
Missouri
University of Missouri, Medical Department.
North Carolina
University of North Carolina College of Medicine.
Wake Forest College, Medical School.
North Dakota
University of North Dakota, College of Medicine.
Oklahoma
University of Oklahoma, School of Medicine.
South Dakota
University of South Dakota, College of Medicine.
Utah
University of Utah, Department of Medicine.
West Virginia
West Virginia University, Department of Medicine.
Wisconsin
University of Wisconsin, College of Medicine.

CLASS B.—MEDICAL COLLEGES NEEDING CERTAIN IMPROVEMENTS TO MAKE THEM ACCEPTABLE

Alabama
Birmingham Medical College.
Arkansas
College of Physicians and Surgeons, Little Rock.
University of Arkansas, Medical Department.
California
College of Physicians and Surgeons, Los Angeles.
Hahnemann Medical College of the Pacific.
Oakland College of Medicine and Surgery.
Georgia
Atlanta College of Physicians and Surgeons.
Atlanta School of Medicine.
Medical College of Georgia.
Illinois
American Medical Missionary College.
Chicago College of Medicine and Surgery (Valparaiso University).
Bennett Medical College.*
Kansas
Kansas Medical College.
Missouri
Barnes Medical College.
Kansas City Hahnemann Medical College.
New York
New York Medical College and Hospital for Women.
Ohio
Cleveland Homeopathic Medical College.
Eclectic Medical Institute.
Toledo University Medical Department.
Pennsylvania
Temple University Medical Department.
South Carolina
Medical College of South Carolina.
Tennessee
College of Physicians and Surgeons, Memphis.
University of Nashville.†
University of Tennessee.†
Memphis Hospital Medical College.
Texas
Baylor University, College of Medicine.
Fort Worth University, Medical Department.
Southwestern University Medical Department.
Wisconsin
Marquette University, Department of Medicine.
Wisconsin College of Physicians and Surgeons.

CLASS C.—MEDICAL COLLEGES WHICH WOULD REQUIRE A COMPLETE REORGANIZATION TO MAKE THEM ACCEPTABLE

California
California Medical College (Eclectic).
College of Physicians and Surgeons, San Francisco.
Georgia
Georgia College of Eclectic Medicine and Surgery.
Hospital Medical College (Eclectic).
Illinois
College of Medicine and Surgery, Physio-Medical.
Hering Medical College.
Jenner Medical College.
National Medical University.
Reliance Medical College.
Kentucky
Southwestern Homeopathic Medical College and Hospital.
Maryland
Atlantic Medical College.
Maryland Medical College.
Massachusetts
College of Physicians and Surgeons, Boston.
Michigan
Detroit Homeopathic College.
Mississippi
Mississippi Medical College.
Missouri
American Medical College.
Ensworth Medical College.
Hippocratean College of Medicine.
St. Louis College of Physicians and Surgeons.
Western Eclectic College of Medicine and Surgery.
Nebraska
Lincoln Medical College.
New York
Eclectic Medical College of the City of New York.
North Carolina
North Carolina Medical College.
Ohio
Pulte Medical College.
Oregon
Willamette University, Medical Department.
Tennessee
Chattanooga Medical College.
Tennessee Medical College.

MEDICAL SCHOOLS FOR THE COLORED RACE

Class A

Howard University, Medical Department, Washington, D. C.
Meharry Medical College, Nashville, Tenn.

Class B

Leonard Medical College, Raleigh, N. C.

Class C

Flint Medical College, New Orleans.
Knoxville Medical College, Knoxville, Tenn.
University of West Tennessee, Medical Department, Memphis, Tenn.
Louisville National Medical College, Louisville, Ky.

CANADIAN COLLEGES

Class A

Manitoba Medical College, Winnipeg.
McGill University, Medical Faculty, Montreal.
Queen's University, Medical Faculty, Kingston, Ontario.
University of Toronto, Medical Faculty, Toronto, Ontario.

Class B

Laval University Medical Faculty, Quebec.
Laval University Medical Faculty, Montreal.
Halifax Medical College, Medical Department of Dalhousie University, Halifax, N. S.

Class C

Western University Medical Department, London, Ontario.

On motion of Dr. Work, seconded by Dr. Chas. Jewett, New York, the report of the Reference Committee on Medical Education was adopted.

* This school has recently been united with the Illinois Medical College and, it is reported, will be developed as the Medical Department of Loyola University.

† These colleges have been merged and are known as the Medical Department of the Universities of Nashville and Tennessee.

The report of the Reference Committee on Amendments to the Constititution and By-Laws was called for. Dr. Alexander R. Craig, Pennsylvania, Chairman, stated that the Committee had been zealously at work, but at this time could only report progress, as the members had by no means completed the immense amount of work assigned to them.

Dr. George W. Guthrie, Pennsylvania, Chairman, presented the report of the Reference Committee on Reports of Officers, as follows:

Report of the Reference Committee on Reports of Officers

To the Members of the House of Delegates of the American Medical Association:

The Reference Committee on Reports of Officers begs leave to report as follows:

I. THE PRESIDENT'S ADDRESS

In compliance with the suggestion of the President, concerning vacancies occurring in the standing committees during the interim between the meetings of the House of Delegates, the Committee recommends that Section 1, Chapter X, of the By-Laws, be amended to read as follows:

CHAPTER X.—COMMITTEES

Section 1.—Classification of Committees.—Committees shall be classified as (a) Standing Committees, (b) Reference Committees, and (c) Special Committees. These committees shall be nominated by the president and elected by the House of Delegates, unless otherwise provided. Any of these committees, acting during the intervals between the sessions of the House of Delegates shall be subject to the Board of Trustees, and any vacancies occurring in any of said committees during the interval between the annual sessions of the Association shall be filled by the president.

II. THE REPORT OF THE GENERAL SECRETARY

The Committee concurs in the recommendation of the General Secretary,—that the Medical Association of the Isthmian Canal Zone be recognized as one of the component bodies of the American Medical Association, and recommends appropriate action by the House of Delegates.

The Committee but voices the unanimous sentiment of this body in expressing regret that the Secretary finds it necessary to ask the House of Delegates to relieve him of the responsibilities of the General Secretary. Dr. Simmons needs no assurance as to the temper and position of this body concerning him personally and officially. It always has stood, and stands to-day, a solid wall behind him, and has no words to express fully its high appreciation of his efficient and faithful services.

The Committee, however, feels that the request of Dr. Simmons should be respected, and, therefore, with great reluctance, recommends that it be granted in order that his great abilities may be exclusively devoted to the duties of Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,—the best medical journal in existence.

III. THE REPORT OF THE BOARD OF TRUSTEES

The Committee has no recommendation to make on this report, except as to the subject of the Public Health Education Committee. The Committee approves the action of the Board in refusing to recognize this Committee, as it had no legal status in the Association; but, in view of the fact that this Committee has been acting in good faith under a misapprehension as to its legal status, and as certain expenses have been incurred under such misapprehension, the Committee recommends that the House of Delegates authorize the Board of Trustees to meet such expenses as it may deem just to said Committee.

Respectfully submitted,
GEO. W. GUTHRIE.
W. B. RUSS.
C. R. P. FISHER.
D. S. FAIRCHILD.
VICTOR H. STICKNEY.

nclusion of the report, Dr. Guthrie moved its adop-
he exception of that part of it pertaining to an

Report of Reference Committee on Miscellaneous Business

Dr. T. A. Woodruff, Chairman, presented the following report of the Reference Committee on Miscellaneous Business.

To the Members of the House of Delegates of the American Medical Association:

Your Reference Committee on Miscellaneous Business recommends that the report of the Committee on the United States Pharmacopeia be received and concurred in.

COMMITTEES CONTINUED ON PHARMACOPEIA, NOMENCLATURE AND ANESTHESIA

In view of the excellent work done by the Committee on Pharmacopeia, we recommend its continuance until the revision of the Pharmacopeia is completed.

Your Reference Committee on Miscellaneous Business would suggest that the report of the Committee on Nomenclature and Classification of Diseases be received. As there are no definite recommendations in this report, no further action is required. It is recommended that the Committee be continued.

Your Reference Committee on Miscellaneous Business recommends that the report of the Committee on Anesthesia be received and the committee continued. We suggest that the Board of Trustees give this committee definite instructions as to the scope and limitations of the investigation.

Respectfully submitted,
T. A. WOODRUFF.
EDWIN WALKER.
E. A. HINES.
E. J. GOODWIN.

On motion, the report was adopted.

Report of the Committee on Organization

To the Members of the House of Delegates of the American Medical Association:

Dr. J. N. McCormack, Kentucky, Chairman, read the report of the Committee on Organization, as follows.

Accounts of my itineraries in New England and the Northwest were given such publicity in Association and state journals at the time that I shall confine this report to the subject of national health legislation, which was put so prominently before the profession by the action of this House two years ago, and has been kept constantly before it by the indefatigable labors of your Legislative Committee since, in an effort to secure a national department of health, the aspiration and hope of this Association for half a century.

MOVEMENT FOR PUBLIC HEALTH LEGISLATION

After years of unselfish and apparently unappreciated effort it came to us unexpectedly that leading laymen all over the country, and the American Association for the Advancement of Science, had taken up the subject of public health legislation and were working on lines parallel to ours, and our forces were soon joined. This lay movement was led by a remarkable man, whom I came to appreciate first in the National Conservation Commission, and of his personality and labors it has become essential that you should know. Irving Fisher, a Jerseyman by birth, graduated from Yale some twenty years ago with higher honors than any other man, except one, had ever received from that institution. At once given one of the most important professorships, he soon developed tuberculosis, went West, and taught for several years in the universities of Colorado and California. An investigator, and student by nature, and vitally concerned in a personal way, he applied himself to the mastery of the laws of health, became a robust man and, fired by a noble zeal to save from, or cure others of, preventable afflictions similar to the one to which he had fallen a victim, he returned to Yale, changed to the field of political economy as best suited to the purposes he had in view, became one of the world's greatest students and writers in this field, organized the American Health League, became the leader of the lay forces, which started out with the avowed purpose of putting a knowledge of the laws of better and cleaner living, the benefactions of modern science, within reach of every hearthstone in this country, as his counterpart, Lord Ashley, had done in England a century before. I was impressed at the outset of our acquaintance that he had not seen the best side of our profession and had some of the prejudices, only more frankly expressed, of the average layman as to its aims and attainments; and asked him to make the same careful study of its plans of organizations and purposes that he had given to other problems, with the result that he soon became one of our most appreciated friends.

HEALTH PLANKS IN NATIONAL PLATFORMS

He joined Dr. Reed and others in securing the insertion of the health planks in the national platforms of the leading political parties, enlisted the active interest of President Roosevelt, leading educators, life insurance, labor, farmer and other great lay organizations, spending his time and means as freely and unselfishly to save others as if his own life or the life of his family were at stake.

FRIENDS IN CONGRESS

Soon another great layman, Senator Robert L. Owen, of Oklahoma, entered the lists as our official advocate in the national senate, largely through the influence of Major W. O. Owen, his brother, a retired medical army officer of ability, long interested in public health work, as have Sternberg, Gorgas, Reed, Carroll, Lazear, White, Blue, Carter, Gihon, in this and other branches of the public service. It has been one of the greatest privileges of my life to be intimately associated with these two lay friends of ours, Owen and Fisher, and knowing them and their unselfish purposes as I have come to do, I ask for them the gratitude and appreciation of the profession and people of this country, which is constantly in my own heart, that this be extended to Dr. Owen, for the important, if less conspicuous, work done by him.

Sent on to Washington by your Legislative Committee, after the great speech of Senator Owen had impressed this country as Gladstone had done England a few decades before, "that care for the public health is the first and highest duty of the statesman," I found many leading men of both houses outspoken in support of the principles of his bill, and a number of our most experienced friends believed that there was an excellent chance to perfect and pass it at the present session of the Congress. After looking over the ground and conferring with Doctors Sower, Wiley, Kober, Woodward, Owen and others (and I have never seen men more devoted and earnest in a cause), the hearings were arranged, and it is believed that few measures of such a nature were ever more ably supported.

OPPOSITION TO THE OWEN BILL

As the time for the hearing drew near an opposition developed, which was so vociferous and claimed so much as to deceive all but the most experienced men in and out of Congress.

Although the national government has no more authority over the practice of medicine outside of the District of Columbia, than the practice of law or farming, that this bill provided for the prevention and not for the cure of disease, and made no provision for putting doctors of any kind in authority over any body or thing, under the cry of medical freedom, the homeopathic, eclectic and practitioners of other schools were gravely informed that we were to be given absolute control of families and homes and that even religious liberty was at stake.

THE OPPOSITION IDENTIFIED

It soon became known that back of all this clamor were the "patent-medicine" people, food adulterators and other interests naturally at enmity with pure drugs, pure food and honesty and decency of method in all such matters, organized into an unholy, corrupt, but futile conspiracy to mislead the people and to break down the profession.

More important was an opposition due to a conflict of interest between the bureaus and divisions directly affected by the proposed transfer to the new health department, about which there might well be honest difference of opinion. This occasioned much anxiety to the friends of the legislation, and the ablest men in the profession came on to Washington and took part in the negotiations to meet the difficulty. These negotiations were continued here, and I am happy to inform you that, under the sagacious leadership of Doctors Welch and Gorgas, great enough to give proper consideration to every interest, an agreement has been reached, we are to have a health department, commensurate with the powers and resources of our government, and in time, our country is to be put in the front rank in the field of preventive medicine.

RESOLUTIONS PROPOSED

In accordance with that agreement, and by authority, I now offer the following:

Resolved, That the President be, and is hereby, authorized to appoint a committee of seven members, which shall be charged with the duty of framing a bill for a national Department of Health, to be presented to the next session of Congress in December, and that this committee shall consider and determine all matters and policies relating to national health legislation, and may invite the cooperation and cooperate with other organizations having the same purpose in view.

Resolved, That the principles of the Owen bill, having for its object the creation of a national Department of Health, now pending in the Senate, and similar bills introduced in the House by Representatives Simmons, Creger and Hanna, be, and are hereby, heartily approved by this Association, and the cordial thanks of the medical profession of the United States, officially represented by it, are hereby tendered to Senator Robert L. Owen, Iriving Fisher and their co-workers for their able and unselfish efforts to conserve and promote the most important asset of the nation, the health and lives of its women, its children and its men, properly understood the greatest economic question now confronting our people.

The members of this Association stand for pure food, pure drugs, better doctors, the promotion of cleaner and healthier homes, and cleaner living for individuals, for the state and for the nation. We believe this to be held as equally true by the reputable and informed physicians of all schools or systems of practice.

We welcome the opposition of the venal classes long and profitably engaged in the manufacture of adulterated foods, habit-producing nostrums and other impositions on the people—to the extent of hundreds of millions of dollars annually—and express our sympathy for the well-meaning men and women who have been misled and worked into hysterics by the monstrously wicked misrepresentations of a corrupt and noisy band of conspirators and who are being used as blind instruments to enable them to continue to defraud and debauch the American people.

Medical science is advancing, especially on its life-saving side, with a rapidity unknown to any other branch of human knowledge. It is known of all men that our members in every community in the United States are unselfishly working day and night, instructing the people how to prevent tuberculosis, typhoid fever and the other diseases from which physicians earn their livelihood. Therefore, we welcome and will wear as a badge of honor the slanders of these unholy interests and their hirelings.

J. N. McCormack, Chairman.

The President stated that if there was no objection this report would be referred to the Reference Committee on Reports of Officers, and as there was none, the report was so referred.

Invitation from Texas

Under the head of new business the General Secretary read the following telegram from Amarillo, Texas: "The profession of the great Pan Handle joins all Texas in a hearty and cordial invitation to hold the next annual session of the American Medical Association within its borders, where ozone and good fellowship are as free as the howl of the festive coyote and password is stiffiene. E. A. Johnson, D. R. Fly, G. L. Thomas."

On motion, the telegram was referred to the Committee on Transportation and Place of Session.

Communication from W. C. T. U.

The General Secretary read a communication from the National Woman's Christian Temperance Union, which was referred, on motion, to the Reference Committee on Hygiene and Public Health.

Resolutions Regarding Coroners

Dr. E. J. Goodwin, Missouri, presented the following resolution, at the request of Dr. R. B. H. Gradwohl, St. Louis, regarding the need for change in the present coroners' system in the United States:

Whereas, The office of coroner, while ancient and honorable, exists to-day as an obsolete relic of what was formerly an office for the holding of property for the crown; and

Whereas, The original intent of holding property for the government has been changed by a slow system of evolution into an office for the determination of the cause of death and responsibility therefor of individuals dying by their own hand, by some one's else hand, by accident and without medical attendance; and

Whereas, The function of the coroner's office to-day is two-fold medical, in so far as determination of the cause of death is concerned, and judicial in so far as determination of the responsibility for this cause of death is concerned; and

Whereas, It is utterly impossible to reconcile these two functions under one heading; and

Whereas, On account of the weird jumble of functions, neither function is properly set out and served; and

Whereas, The functions have been divided, on this account, in some commonwealths, notably Massachusetts, by abolishment of the office of coroner, relegating the medical duties of that office to a medical examiner, and turning over the legal duties to the district attorney's office, resulting in a vast improvement over the older system, with credit to the medical profession, in view of the fact that the medical duties of the office are better performed under this system; therefore, be it

Resolved, That this House of Delegates go on record as favoring a system of investigation which will divorce the medical from the judicial functions of the coroner's office, and that the medical examiner system, such as in force in the commonwealth of Massachusetts, may well be imitated in seeking this new system.

On motion of Dr. Alexander R. Craig, Pennsylvania, the preambles and resolution were referred to the Reference Committee on Hygiene and Public Health.

Committee for Resolution on Dr. Ricketts

Dr. T. D. Tuttle, Montana, called attention to the death of Dr. H. T. Ricketts, who was a martyr to science. Montana had a small number of physicians who had done the best they could to honor Dr. Ricketts' name by establishing in their society a permanent Howard T. Ricketts' prize. He moved that the President appoint a committee of three to draft suitable resolutions in regard to Dr. Ricketts.

The motion was seconded.

Dr. G. B. Young, U. S. P. H. and M.-H. Service, pointed out that Dr. Ricketts was not the only physician who fell a martyr to zeal for scientific investigation in connection with typhus fever in Mexico, as he understood a physician from the State of Ohio had also died from that disease after his return to Ohio. This same physician of the U. S. P. H. and M.-H. Service had previously contracted yellow fever, dengue, smallpox, in Mexico, and this time typhus fever.

The motion was carried.

The President appointed as members of this Committee: Drs. T. D. Tuttle, Montana; Frank Billings, Illinois, and Alexander Lambert, New York.

On motion, the House of Delegates then adjourned until 3:30 p. m. Wednesday.

Fourth Meeting—Wednesday Afternoon, June 8

The House of Delegates met at 3:30 p. m. and was called to order by the President. The Secretary called the roll. The minutes of the previous meeting were read, corrected and approved.

Report of the Public Health Education Committee

A resolution was introduced, asking the privilege of the floor for Dr. Rosalie Slaughter Morton, to present the work of her committee. This was granted.

President Welch reminded the House that this committee was not regularly created by the Association and therefore not technically a committee of the Association or of the House of Delegates. He then introduced Dr. Morton, Chairman of the Committee, who presented the following report:

To the Members of the House of Delegates of the American Medical Association:

In presenting to you the work of the Public Health Education Committee, created in accordance with a resolution passed unanimously by you on June 10, 1909, and named according to the phraseology of the resolution, we wish you to know that we have realized the great responsibility resting on us to work worthily with you, who represent the vast number of American physicians who are leaders in scientific achievement and medical work for the good of humanity. We have felt it a privilege to do a piece of work which we hoped would be of some service to your many other active committees and fit like a piece of mosaic into the great constructive whole. We understood that we were commissioned to do this work because as members of many organizations we come in contact with large bodies of earnest, public-spirited women who realize the importance to their children of high community standards of health. We have given in the one year of our existence 2,250 lectures free from technicalities and filled with sound teaching regarding public health, and have reached 102,575 people.

TIME RIPE FOR THIS WORK

The timeliness of the action taken by the House of Delegates of the American Medical Association is emphasized by the fact that, as Dr. George W. Wagoner of Johnstown, Pa., said lately, in his presidential address before the Medical Society of the State of Pennsylvania: "Doctors are losing the confidence of and receiving criticism from the laity." This is largely due to the fact that throughout the country the public is being exploited by pseudo-scientists who affirm that we, the so-called "drug-doctors," are commercially interested in keeping the people ill, while they are working to prevent disease. The laity is much interested in public health education. The psychologic moment has come, and it would be a serious reflection on our profession if we did not now educate the public to a thorough appreciation of the position of the doctor as the protector of the health of the community. Instead of doing this individually or in isolated groups, through a national movement from within the American Medical Association, we emphasize the fact that this desire to educate the public for the prevention of disease is general among physicians. In presenting to you the work of this committee we ask your hearty cooperation as individuals and as members of the American Medical Association in this work of service to our country.

Another year the work would have wider usefulness, as in many organizations which have sought our cooperation, the general lecture programs for this year were completed before our committee work began. They, however, welcome the opportunity to have practical instruction on public health subjects another year and there are many requests in all parts of the states for a continuation of the work.

In the printed report, copies of which you received yesterday, you will find details of the work which is now well organized and going forward in forty states. You will see that a small leaflet has been used to set forth the object and plan of work, as follows:

THE CREATION OF THE COMMITTEE

This plan of work is the result of the following resolution unanimously passed by the House of Delegates of the American Medical Association at their annual meeting held in June, 1909, in Atlantic City, N. J.

> Whereas, The American Medical Association, not only as one of its declared purposes, but by numerous lines of activity, many of them connected with the Section on Hygiene and Sanitary Science, stands committed to the education of the public with respect to the nature and prevention of disease; and
>
> Whereas, The demand for such popular education with respect to tuberculosis, cancer, typhoid fever and other decimating diseases has become urgent; therefore, be it
>
> *Resolved*, That the women physicians, members of the American Medical Association, be, and they are hereby, requested to take the initiative individually in their respective associations in the organization of educational committees to act through women's clubs, mothers' associations and other similar bodies, for the dissemination of accurate information touching these subjects among the people, and that they be requested to submit to the House of Delegates a yearly report of such work, and to elect from among their number a committee to take charge of the same.

SUBJECTS DISCUSSED BEFORE THE PUBLIC

In accordance with this resolution, physicians from all over the United States held a meeting in New York City, July 20, 1909, when the Public Health Education Committee of the American Medical Association was formed and officers were elected. Many physicians, both men and women, who have already done a great deal of work individually along these lines have now promised, through this committee, to give gratuitously, from time to time, during the ensuing year, as they may be requested to do so by women's clubs, mothers' and teachers' organizations, young women's Christian associations, church and social settlement clubs, etc., addresses on the following subjects:

1. The cause and prevention of ordinary colds.
2. The value of pure food and the physiology of digestion.
3. The chemistry and economic value of food.
4. The care of the food at home.
5. The relation of pure water to the public health.
6. Water-borne diseases.
7. The value of exercise and rest to the public health.
8. The causes and prevention of nervous exhaustion and prostration.
9. The use and abuse of stimulants and narcotics.
10. The prevention and cure of tuberculosis.
11. The air we breathe and the value of ventilation.
12. The relation of flies, mosquitoes, water bugs and other insects to public health.
13. Pure milk and infant hygiene.
14. The hygienic management of nervous children.
15. The relation of teeth to good health.
16. Prevention of some of the commoner skin diseases.
17. The importance of early diagnosis and treatment of adenoids.
18. The causes and prevention of deafness.
19. The prevention of Fourth of July injuries and tetanus.
20. The prevention of acquired deformities.
21. The causes and prevention of blindness.
22. The causes and results of eyestrain.
23. How to instruct children regarding the origin of life.

24. The responsibility of girlhood to motherhood in the care of the health during the menstrual period.
25. Pregnancy and the menopause.
26. The value of early diagnosis of cancer in women.
27. The responsibility of boyhood to fatherhood.
28. Social hygiene—how parents may protect their sons and daughters from immorality.

COOPERATION WITH CLUBS

In order to simplify this work it is suggested that each club or organization wishing one or more of the above lectures on the prevention of disease, from a hygiene committee whose duty it shall be to arrange the date, choose the topic or topics and communicate with the Public Health Education Committee, who will on receiving such requests ascertain which of the physicians, who have promised this public service, may be able to arrange their engagements to be free to deliver the address or addresses. As the constant demands of private and charity practice leave the physician little time for outside work, it is hoped smaller clubs will have joint meetings in order that this work, designed to lessen suffering and save life, may be as far-reaching as possible.

Throughout the United States such excellent work has been done to assist many of the boards of health, and also independently, by public-spirited men and women in work for pure milk, clean streets, prevention of tuberculosis, etc., etc., that we hope to have their hearty cooperation in this wider work for the public good.

CENTRAL COMMITTEE

Hon. Chairman, S. R. A. Dolley, M.D., Rochester, N. Y.
R. S. Morton, M.D., Chairman, New York City.
E. Garrigue, M. D., Secretary, New York City.
A. Gregory, M.D., Treasurer, New York City.
L. H. South, M.D., Kentucky.
S. C. Buckley, M.D., Illinois.
R. T. Bullard, M.D., California.
A. L. Hamilton, M.D., Massachusetts.
M. Holliday, M.D., Texas.
L. L. Liebhardt, M. D., Colorado, State Secretary of the Public Health Education Committee.

We have covered a large field of education and part of the success of the work has been due to the fact; for not only have the topics been presented in a number of states but their multiplicity has made it possible for many physicians to take part in the work, each bringing the prestige of an expert to add to the force of the teaching.

THE WORK IN NEW YORK AS A SAMPLE

The work in New York City may be taken as a type of the whole. Leaflets were distributed among all club, charity and social organizations, and as a result many requests came from them for a single lecture or a series of lectures; on pages 66 and 67 of our report you will see how wide was the variety of groups who wished this education, from the colored orphan asylum to the most exclusive clubs.

The plan of work was then brought before the Medical Society of the County of New York and a committee of both men and women appointed to cooperate with the American Medical Association committee.

The members are as follows:

Thomas Darlington, M.D.
Henry P. DeForest, M.D.
Norman E. Ditman, M.D.
Caroline S. Finley, M.D.
Alice Gregory, M.D.
Luther H. Gulick, M.D.
H. Seymour Houghton, M.D.
John H. Huddleston, M.D.
Woods Hutchinson, M.D.
Abraham Jacobi, M.D.
Elizabeth C. Jagle, M.D.
John J. Moorehead, M.D.
Prince A. Morrow, M.D.
Grace Peckham Murray, M.D.
William H. Park, M.D.
Angenette Parry, M.D.
Victor C. Pedersen, M.D.
Godfrey R. Pisek, M.D.
William M. Polk, M.D.
Charles H. Richardson, M.D.
Louis Livingston Seaman, M.D.
Isabelle Thompson Smart, M.D.
Fielding Lewis Taylor, M.D.
Frank Van Fleet, M.D.
Antoine P. Voislawskey, M.D.
James J. Walsh, M.D.
Anna W. Williams, M.D.
John A. Wyeth, M.D.
Grace C. Prior Yankauer, M.D.

And under their auspices a series of 12 lectures have been given, each topic being presented in its different aspects by different physicians, so leaving in the minds of the audience a constructive whole.

The seating capacity of the auditorium was for 300, but adjoining rooms had to be opened on all occasions, and there was scarcely standing room, for the audiences often numbered over 500 persons, representatives of every class and station in life.

A similar course of lectures was given in Brooklyn with equal success, and in many other places the work has gone forward with the cordial and valuable cooperation of the County Medical Societies and the help of many public-spirited individuals.

RESULTS OF A YEAR'S WORK

The results have been that the laity in many places have come to a more thorough understanding of the regular physician's position, as unselfish advisor and trained scientist, and therefore the prejudice and spirit of opposition which have been aroused by antivivisectionists and others have been lessened.

We have been able to accomplish a great deal because many of our committee members, and also members of women's clubs have organized hygiene committees throughout the United States and are now in touch with 900,000 women. In each locality these committees are under the guidance of a chairman, who is also a member of the Public Health Education Committee of the American Medical Association, in this way forming a most valuable alliance for the prevention of disease between the mothers of America and the physicians who are willing to give their time and strength in teaching these mothers how to protect their children and all who are under their care.

THE REASONABLENESS OF THIS SERVICE

Since each of us gives an average of 100 hours a year in clinical work for the gratuitous curing of disease, your committee feels that it is reasonable to request that other physicians should be willing to spend from one to four hours a year in gratuitous teaching, for the prevention of disease, and with this small effort on the part of every one the aggregate benefit to humanity will be enormous. Our financial statement and our indebtedness to the Russell Sage Foundation will be found on page 107 and the work we have done in cooperation with other organizations on pages 10 and 11.

There are sixty-eight national organizations for social betterment. The most valuable asset to the nation is health. This is an age of philanthropy; the greatest and most far-reaching benefit is medical philanthropy, and in this committee working at your request we have felt it our duty to you to show the American Medical Association ready to take its place in this important line of the nation's work, for no other organization can be so fitted to lead a campaign for the promotion of the health of American citizens as the noble body of physicians this House of Delegates represents.

Many requests for lectures have come to us from labor unions and other groups of men, especially those in trades leading to pulmonary infection, and as we believe all work for the good of the race is best done by men and women working together; in closing this brief report we wish to request that the men members of the American Medical Association who have been working with us in county medical societies committees, and other American Medical Association men interested in public health education, be permitted to become members of this committee.

Assuring you of the privilege I have felt it to be to have even a small part in the good work which has gone forward under your auspices, this report is respectfully submitted.

Rosalie Slaughter Morton, *Chairman.*

On motion of Dr. Samuel Wolfe, Pennsylvania, the report was referred to the Reference Committee on Hygiene and Public Health.

APPROPRIATION RECOMMENDED FOR PUBLIC HEALTH EDUCATION

Dr. Samuel Wolfe, Pennsylvania, in connection with the above report, presented the following resolutions:

Whereas, The report of the Public Health Education Committee, formed in response to a resolution passed by the House of Delegates at its last session in Atlantic City, shows a widespread interest in the education of the general public in matters pertaining to health; and

Whereas, Great opportunity for valuable work lies before the Public Health Education Committee; be it

Resolved, That a standing committee composed of men and women members of the American Medical Association be appointed by the President to carry on public health education work as outlined by the report of the special Public Health Education Committee; and be it further

Resolved, That the Board of Trustees be directed to appropriate a sum of money sufficient to enable this committee to continue and develop its work.

On motion, the resolutions were referred to the Board of Trustees.

Report of the Reference Committee on Legislation and Political Action

Dr. J. W. Clemmer, Ohio, Chairman, presented the following report of the Reference Committee on Legislation and Political Action:

To the Members of the House of Delegates of the American Medical Association:

Your committee has carefully considered the various matters presented to it and respectfully report as follows: We congratulate the Committee on Uniform Medical Practice Act on the gratifying progress made in that matter and recommend that the committee be continued.

We invite the attention of the house to the exceedingly gratifying progress made during the past year in the direction of defeating the optometry bills in five states, a very welcome break in the success which has hitherto followed the efforts of the advocates of the objectionable optometric legislation. A success which has resulted in securing the passage of optometry bills in twenty-two states. We consider that this desirable outcome of the past year's work is an indication of what can be done by an aroused profession and urge our members to increased efforts along this line.

The success of the movement to prevent optometry legislation is a source of greatest satisfaction and reflects the highest credit on the committee having the matter in charge, and especially on Dr. Gay, whose untiring efforts in the preparation and circulation of literature on the subject have been so potent a factor in preventing optometry legislation.

COMMENDATION OF LEGISLATIVE BUREAU

Your committee especially commends the work done by the Bureau of Medical Legislation in extending its valuable aid to state and other medical bodies, and strongly recommends that this work be still further prosecuted and respectfully urges that the trustees take the necessary steps to secure early publication of the proposed hand-book of court decisions in regard to medical practice, and similar legislation.

We congratulate the Association and the Committee on the Carroll Fund on the striking success which has crowned their efforts and recommend the continuance of the committee until they can complete the transfer of their trust.

We congratulate the National Legislative Committee in securing the promise of the cooperation of the Civic Federation and its branches, and that of the state commissions on uniform laws. Their assistance should be a great value in framing and securing the passage of proper laws in regard to medical practice and other subjects in which the profession is especially interested.

As the report of the Committee on Patents and Trade-marks was fully considered at the Atlantic City session in 1909 by both the Reference Committee and the House of Delegates, we agree in the recommendation of the said committee that the question of further action be referred to the Legislative Committee and the special committee discharged.

In regard to that portion of the report of the Legislative Committee which refers to the National Public Health Legislation, your committee indorses the satisfaction expressed by the Legislative Committee in the great public interest which has been aroused in the matter, and we respectfully recommend that the proper agencies of the Association take the necessary steps to increase this interest, and to correct the misapprehension, instigated by unscrupulous and venal interests, as to the purposes of national health legislation. In view of the statement made in the report of Dr. McCormack and the reference of that report to another committee, we do not feel that we are called on to make any definite recommendations in regard to legislation.

As the report of the Board of Instruction on Medical Subjects contains the statement that its work has been largely held in abeyance awaiting the organization of the Council on Public Health, Publicity and Legislation, which will prevent duplication of activities and results in economy of administrative effort, and as the report of the committee in regard to this proposed Council has been referred to another committee no recommendation is necessary.

We recommend to the House the passage of the resolution adopted by the Legislative Council at its Chicago meeting, as follows:

> *Resolved*, That the conference recommends that state food laws be so amended as to provide that advertisements of foods and drug products correspond with the labels; and that the drug section of the model pure food laws conform as closely as possible to the national Food and Drugs Act.

We recommend that the resolutions presented by Dr. Sanders on behalf of the Medical Association of the State of Alabama be referred to the careful consideration of the committee on National Health Department Legislation which we understand is to be appointed by the President.

PRAISE FOR DR. REED'S WORK

While the personal communication of Dr. Reed, for eight years Chairman of the Legislative Committee, does not come before your Reference Committee for review, the committee feels that the Association should take this opportunity to express its appreciation of the great, untiring, loyal and faithful services of Dr. Reed in promoting the successful work of his committee, services which have involved the greatest sacrifice of both his time and thought, to voice its deepest regret that Dr. Reed feels it impossible to continue to lead in this work, to state that the Association gladly accept his proffered offer of cooperation in legislative activities in the future in some other capacity, and to express to him its sincere thanks for his invaluable services and the loyal spirit which has inspired him.

J. W. Clemmer, *Chairman.*

It was moved that the report be adopted and the recommendations of the committee be concurred in. Seconded.

The report was discussed by Dr. C. S. N. Hallberg, and Dr. G. B. Young, Illinois, after which Dr. Hallberg moved to amend by adding the words, "provided all drugs conform to the standards of the United States Pharmacopeia and the National Formulary."

The amendment was seconded, accepted, and the original motion as amended was carried.

Report of the Reference Committee on Hygiene and Public Health

The Secretary read the following report of the Reference Committee on Hygiene and Public Health:

To the Members of the House of Delegates of the American Medical Association:

ACTION ON CORONERS DEFERRED A YEAR

Your committee, to which was referred the resolution regarding the need for change in the present coroners system in the United States, has carefully considered the same and begs to report that owing to the necessity of careful investigation of the legal and other phases of this question, it is impossible to make a satisfactory report at this time, and it is recommended that this resolution be referred to the permanent Committee on Medical Legislation with instructions to thoroughly inquire into all points, both legal and medical, which may be related to this subject, and to report on the same at the next annual meeting.

JOURNAL COMMENDED FOR JULY FOURTH WORK

The Reference Committee on Hygiene and Public Health, to which was referred the resolution commending the statistical and editorial work of The Journal of the American Medical Association in reference to the fatalities and casualties resulting from the present methods of celebrating the Fourth of July, respectfully recommend that the resolution be adopted.

William N. Wishard, *Chairman.*

On motion, the report was adopted.

Report of Reference Committeee on Reports of Officers

Dr. George W. Guthrie, Pennsylvania, Chairman, read the following report of the Reference Committee on Reports of Officers with reference to the report of the Committee on Organization:

To the Members of the House of Delegates of the American Medical Association:

DEPARTMENT OF HEALTH BILL URGED

Your committee wishes to congratulate Dr. J. N. McCormack and his co-workers on the excellent and efficient manner in which they have conducted the work of organization and education during the past year. We recommend that the work along these lines be broadened and extended; we recommend the adoption of the report of the Committee on Organization, including the resolution embodied therein, as follows:

SPECIAL COMMITTEE AUTHORIZED

Resolved, That the President be, and is hereby, authorized to appoint a committee of seven members, which shall be charged with the duty of framing a bill for the National Department of Public Health, to be presented to the next session of Congress, in December, and that this committee shall consider and determine all matters and policies relating to national health legislation, and may invite the cooperation and cooperate with other organizations having the same purpose in view.

George W. Guthrie, *Chairman;*
W. B. Russ.
C. R. P. Fisher,
D. S. Fairchild,
Victor H. Stickney.

At the conclusion of the report Dr. Guthrie moved its adoption.

Seconded.

Dr. Frank Billings, Illinois, moved to amend that the President, Dr. Welch, be named as a member of the committee.

This motion was seconded by several.

The amendment was accepted and the original motion as amended was carried.

Resolutions Regarding Owen Bill

Dr. Guthrie, Pennsylvania, presented the following resolution, which, on motion of Dr. W. W. Richmond, Kentucky, was unanimously adopted by a rising vote:

Resolved, That the principles of the Owen Bill, having for its object the creation of a National Department of Health, now pending in the Senate, and similar bills introduced in the House by Representatives Simmons, Creager and Hanna, be, and are hereby, heartily approved by this Association, and the cordial thanks of the medical profession of the United States, officially represented by it, are hereby tendered to Senator Robert L. Owen, Irving Fisher and their co-workers for their able and unselfish efforts to conserve and promote the most important asset of the nation, the health and lives of its women, its children and its men, properly understood the greatest economic question now confronting our people.

The members of this Association stand for pure food, pure drugs, better doctors, the promotion of cleaner and healthier homes, and cleaner living for individuals, for the state and for the nation. We believe this to be held as equally true by the reputable and informed physicians of all schools or systems of practice.

We welcome the opposition of the venal classes, long and profitably engaged in the manufacture of adulterated foods, habit-producing nostrums and other impositions on the people, to the extent of hundreds of millions of dollars annually, and express our sympathy for the well-meaning men and women who have been misled and worked into hysterics by the monstrously wicked misrepresentations of a corrupt and noisy band of conspirators, and who are being used as blind instruments to enable them to continue to defraud and debauch the American people.

Medical science is advancing, especially on its life-saving side, with a rapidity unknown to any other branch of human knowledge. It is known of all men that our members in every community in the United States are unselfishly working day and night, instructing the people how to prevent tuberculosis, typhoid fever and the other diseases from which physicians earn their livelihood. Therefore, we welcome and will wear as a badge of honor the slanders of these unholy interests and their hirelings.

Report of the Reference Committee on Miscellaneous Business

Dr. Edwin Walker, Indiana, read the report of the Reference Committee on Miscellaneous Business, as follows:

To the Members of the House of Delegates of the American Medical Association:

NEW OFFICIAL BUTTON

The Reference Committee on Miscellaneous Business, to which was referred the report of the Committee on Insignia for the American Medical Association, respectfully reports that it has taken up this question with both committees and thoroughly discussed this matter.

Both committees are unanimous in the opinion that the color of the new emblem should be scarlet and gold and that the emblem should be the knotty rod, entwined with the serpent. We recommend that the button should be circular, one-half inch in diameter, the central portion scarlet enamel, on which shall be placed the serpent, and the knotty rod in gold, this to be surrounded by a band of gold, in which the letters "A. M. A." should appear in scarlet enamel.

T. A. Woodruff,
Edwin Walker,
Ridgely B. Warfield,
E. J. Goodwin.

On motion, the report was adopted.

Report of the Committee on Awards

Dr. E. E. Southard, Massachusetts, read the following report of the Committee on Awards:

To the Members of the House of Delegates of the American Medical Association:

We recommend the award of a gold medal to Dr. Claude A. Smith, Atlanta, Ga., for an exhibit bearing on experimental researches on hook-worm disease.

We recommend that no medal be awarded for work in clinical surgery.

We recommend that certificates of honor be awarded to the following exhibitors:

1. University of Minnesota.
2. St. Louis University—Exhibit of Research Work.
3. St. Mary's Hospital, Rochester, Minn.
4. St. Louis City Hospital.
5. Indianapolis Department of Public Health.
6. University of Michigan.
7. Monlogos of Skin Disease: Dr. Honwink, St. Louis.
8. Special Committee on Prevention of Blindness, New York.
9. Northwestern University, Chicago.
10. St. Louis Medical History Club.

Respectfully yours,

E. E. Southard.
T. D. Coleman.
H. H. Young,
Committee on Awards for Scientific Exhibits.

On motion, the report was adopted.

Resolutions on Dr. Ricketts

Dr. T. D. Tuttle, Montana, Chairman of the Committee appointed to draft suitable resolutions in regard to the late Dr. Ricketts, read the following:

Whereas, Howard Taylor Ricketts, a member of the American Medical Association, lost his life on May 3, 1910, from typhus fever, contracted while engaged in an investigation of that disease in the City of Mexico; and

Whereas, He sacrificed himself in the study of a preventable disease and in the interest of the health and lives of the human race; and

Whereas, His masterly attainments as a scientific worker in this and other fields rendered his life of inestimable worth to the medical profession and the world at large; therefore, be it

Resolved, That the American Medical Association, in convention assembled, herewith express its high appreciation of the ideals, the efforts and the achievements of this brilliant investigator, and its deep sorrow at the loss of a most brilliant investigator, and its deep sorrow at the loss of a most valued and cherished member; and

Resolved, That we herewith express our sorrow in the death of Dr. Conneffe, of Ohio, who lost his life as a result of infection with typhus fever while working with Dr. Ricketts in Mexico City; and

Resolved, That these resolutions be spread on the minutes of this Association and published in The Journal.

T. D. Tuttle.
Frank Billings.
Alexander Lambert.

On motion, the resolutions were adopted by a rising vote.

Associate Members Elected

Dr. J. H. White, Louisiana, presented the following communication from the Section on Preventive Medicine and Public Health:

To the Members of the House of Delegates of the American Medical Association:

The officials of the Section on Preventive Medicine and Public Health nominate for associate membership in the American Medical Association John M. Glenn, New York, Director of the Russell Sage Foundation.

Marshall Langton Price, Secretary.
J. N. Hurty, Chairman.

On motion, the nominee was elected to associate membership.

The Section on Pharmacology and Therapeutics recommended that Leonard A. Seltzer, Detroit, be made pharmaceutical member, and on motion, the recommendation was concurred in.

The Section on Pathology and Physiology nominated for associate membership P. B. Hawk, Urbana, Illinois; A. J. Carlson, Chicago, and Leo Loeb, Philadelphia, and, on motion, the nominations were confirmed.

Resolution on Optometry, Blindness, Etc.

Dr. Chas. Jewett, New York, offered the following resolution:

Resolved, That we deem it extremely unfortunate that Columbia University, New York, related as it is to medical education, should have seen fit to establish a school of optometry for opticians, thus virtually giving countenance to the practice of medicine by persons who have not received a medical education.

On motion, this resolution was referred to the Judicial Council.

RESOLUTIONS FROM THE SECTION ON OPHTHALMOLOGY

Dr. T. A. Woodruff, Illinois, presented the following resolutions from the Section on Opthalmology:

Whereas, In many states examining boards of optometrists have been legalized and are assuming in their examinations of students prerogatives of the medical profession; and

Whereas, In a number of states either the governor or the board of medical examiners has appointed ophthalmologists to serve with opticians in examining candidates for license in the mechanical examination of eyes (so-called optometry); and

Whereas, Such affiliations on the part of medical men are practically endorsements of the optician's claim that laymen without medical education are capable of prescribing for errors of refraction; and

Whereas, These underlying ocular defects can only be diagnosed and corrected by the educated physician, who can appreciate this special work, by functional and objective examination; and

Whereas, This matter assumes importance because in many states the examining optician without medical training or responsibility is seeking legal authority to make diagnosis of and prescribe for ocular defects; therefore, be it

Resolved, That the Section on Ophthalmology of the American Medical Association memorializes its House of Delegates with the following petition:

The Section prays: That the House of Delegates express its disapproval of ophthalmologists serving with opticians on boards examining men who have not taken medical courses endorsed by the Association of American Medical Colleges and considers the acceptance of such appointment by ophthalmologists as contrary to the spirit of the code of ethics of the American Medical Association.

That the House of Delegates urge on all members of the American Medical Association, first, that legal recognition of the optician to diagnose the condition of the eye is an infringement on medical practice laws, and therefore should not be sanctioned by any state or institution; second, that referring patients to opticians by a physician should be deprecated because it is not only exposing them to the risk of incomplete diagnosis and unnecessary suffering, but is aiding and abetting men who have no medical education, in their acknowledged and open efforts to enter on an important field of special medical practice.

Furthermore, the House of Delegates is memorialized to request the American Medical Association to publish a history of so-called optometry and optometry colleges, and that such pamphlet be sent to officials of state medical societies and medical men interested in defeating the efforts of these men to enter the medical profession by false pretenses.

The resolutions include the recommendation for the appointment of a committee of two who are members of the Section on Ophthalmology to furnish the necessary data.

RESOLUTIONS ON TEACHING IN MEDICAL COLLEGES OF INFECTIOUS EYE DISEASES AND OF REFRACTIVE ERRORS

Whereas, The refracting of human eyes is an important part of medical practice;

Whereas, The Section on Ophthalmology of the American Medical Association recommends that "every general practitioner should have the training in ophthalmology which will enable him to manage infectious diseases of the eye and its refractive defects."

Resolved, That the House of Delegates of the American Medical Association:

1. Requests its Council on Medical Education to arrange a curriculum able to equip medical students with such training, and recommends medical colleges to adopt the same.
2. Approves of the state registration boards, now requiring it for license; and
3. Advises like action by other state registration boards at an early date.

RESOLUTIONS REGARDING THE VISUAL REQUIREMENTS OF PILOTS

The following resolutions were unanimously adopted by the Section on Ophthalmology:

Whereas, Investigation has shown that the visual requirements of pilots in the United States under both federal and state supervisions are vague and inadequate, it is recommended that the American Medical Association, through its President, shall appoint a commission from its body, including members from the Section on Ophthalmology, to confer with the Department Commission of Commerce and Labor, and with the Marine-Hospital Service to unite in establishing proper visual standards and tests to govern these public servants; and, further, that the subject under discussion be brought before the House of Delegates with the request that that body give its official sanction and support to the purposes of the commission; and, further, that the present chairman of the Section on Ophthalmology be made a member of the commission.

RESOLUTIONS REGARDING A COMMITTEE ON BLINDNESS

Whereas, The American Medical Association has at present a Committee on Ophthalmia Neonatorum, the purpose of which is the prevention of blindness from this disease; and

Whereas, Trachoma, industrial accidents, intermarriage of the blind and wood alcohol amblyopia are also preventable causes of blindness; therefore, be it

Resolved, That the House of Delegates be requested to appoint a "Committee on the Prevention of Blindness," the membership of which shall consist of the chairman of the Committee on Ophthalmia Neonatorum and such other members for the investigation of the above causes of blindness as the President may appoint. This committee shall invite the cooperation of the American Ophthalmological Society and similar organizations.

On motion, these resolutions were referred to the Reference Committee on Hygiene and Public Health.

Resolution on Year Book

Dr. Alexander Lambert, New York, offered the following:

Whereas, Representatives of the learned societies of the United States of the various professions have met and decided to publish an American Year-Book, in which the advancements in knowledge in all professions shall annually be published; therefore, be it

Resolved, That the House of Delegates of the American Medical Association authorizes the Board of Trustees to appoint a member to serve on the supervisory board of the American Year-Book.

On motion, this resolution was referred to the Board of Trustees.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. Alexander R. Craig, Pennsylvania, read the report of the Reference Committee on Amendments to the Constitution and By-Laws.

To the Members of the House of Delegates of the American Medical Association:

The Reference Committee on Amendments to the Constitution and By-Laws beg to submit the following report of the House of Delegates on the matters which have been referred to them for their consideration.

In the report of the Committee on Uniform Regulation of Membership and from other sources a number of proposed changes in the Constitution and By-Laws came before this Reference Committee and we recommend the adoption of the appended suggestions. We recommend the substitution of the following change in Article 4 of the Constitution for that offered at the last annual session of the House of Delegates.

Article IV.—Amend the present article to read as follows: State and territorial associations which have or which hereafter may become organized in accordance with the general plan of organization of the American Medical Association, and which have declared by resolution their allegiance to the said American Medical Association and which shall agree with other state and territorial medical associations to the formation and perpetuation of the House of Delegates of the American Medical Association, shall be recognized as constituent associations on acceptance of their application for recognition by the House of Delegates.

Amendments to the By-Laws

Chapter I.—Membership

Section 1. Classes of Members.—There shall be three classes of members: Members, associate members, and honorary members.

Sec. 2. Members.—Any physician reported as a member in good standing of the constituent association by the secretary of that association, and who shall make application on the prescribed form, and who shall have paid the annual assessment and the subscription to The Journal of the American Medical Association for the current year, shall be a member.

Commissioned medical officers of the United States Army, United States Navy, and the United States Public Health and Marine Hospital Service, shall be members of this Association so long as they retain their connection with their respective service, and shall not be required to pay dues and shall not receive The Journal of the American Medical Association except by personal subscription.

Sec. 3. Tenure of Membership.—Membership in this Association shall continue only so long as the individual is a member in good standing of the constituent association of the state in which he resides. When the General Secretary shall be officially informed by the secretary of the constituent association of the state in which a member resides that he is *not in good standing*, the General Secretary shall remove his name from the membership roll of the American Medical Association and shall notify him of the action taken, together with the reason therefor.

Sec. 4.—A member who becomes a resident of another state, to retain his membership in the American Medical Association, must become a member in the constituent association of the state to which he has removed within one year following his change of residence.

Sec. 5. Delinquency.—Any member who, for one year, has failed to pay his annual assessment and the subscription to The Journal, shall forfeit his membership thirty days after notice from the General Secretary has been mailed to his last known address.

Sec. 6.—Any former member who complies with Section 2, Chapter 1, shall be reinstated on payment of his current indebtedness.

Sec. 7. Associate Members.—The following may be elected in accordance with Section 4, Chapter VII, to associate membership: Physicians who are members of chartered national medical societies of foreign countries adjacent to the United States; dentists holding the degree of D.D.S. who are members of state or local dental societies; and pharmacists who are active members of the American Pharmaceutical Association.

Sec. 8. Honorary Members.—Physicians of foreign countries may be elected honorary members by the House of Delegates in accordance with Section 4, Chapter 7.

Sec. 9. Invited Guests.—Scientists may be invited by the general officers or by the officers of a Section to attend any annual session and to take part in the scientific work. They shall be designated as invited guests and be entitled to participate in the scientific and social functions.

Chapter II.—Registration

Section 1.—No member shall be eligible to register at an annual session until he has paid all of his current indebtedness.

No member shall take part in the proceedings of the Association or of any of the Sections until he has registered his name and address in the registration office.

A member on registering shall designate the Section in which he wishes to be enrolled, but no member shall register in more than one Section at any annual session.

Chapter IV.—Qualifications, Term, Apportionment and Registration of Delegates

Sec. 2. Term.—Delegates and alternates from constituent associations shall be elected for two years. Constituent associations entitled to more than one representative shall elect them so that one-half, as near as may be, shall be elected each year. Delegates and alternates elected by the Section, or delegates appointed from the United States Army, the United States Navy and the United States Public Health and Marine-Hospital Service, shall hold office for one year.

Sec. 3. Apportionment of Delegates.—At the annual session of 1903, and every third year thereafter, the House of Delegates shall appoint a committee of five on re-apportionment of which the President and General Secretary shall be members. This committee shall apportion the delegates among the constituent associations in accordance with Article 5, Section 2, of the Constitution, and in proportion to the membership of each constituent association on April 1 of the year in which the apportionment is made, as shown by the certificates of membership submitted by the secretary of the constituent associations. This apportionment shall take effect at the annual session next succeeding that at which it is made, and shall prevail until the next triennial apportionment, whether the membership of the constituent associations shall increase or decrease.

Sec. 4. Registration of Delegates.—Each delegate before being seated shall deposit with the Committee on Credentials a certificate signed by the secretary under the seal of the constituent association, stating that he has been legally and regularly elected a delegate to the American Medical Association. Each delegate from a Section shall present credentials signed by the chairman and secretary of the Section which he represents. Each delegate from the government services shall present credentials from the surgeon-general of the department which he represents.

Sec. 5. A Delegate Once Seated to Retain His Seat for the Entire Session.—The credentials of a delegate having been accepted by the credentials committee and his name placed on the roll of the house, he shall remain as the duly accredited delegate of the body which he represents until final adjournment of the session and his place shall not be taken by any other delegate or alternate.

Chapter IV.—Procedure of House of Delegates

Sec. 2. Limit of Time for Introduction of New Business.—No new business shall be introduced into the House of Delegates after the second day of the annual session (third day of the House of Delegates), unless with unanimous consent; and such new business, whether in the form of a motion, a resolution, or a memorial, shall require a two-thirds affirmative vote for adoption.

Chapter VI.—Meetings of the House of Delegates

Sec. 2. Special Sessions.—Special sessions of the House of Delegates shall be called by the president on a written request of at least twenty-seven members of the last House of Delegates, provided that they represent the majority of the constituent associations. When a special session is called by the president the general secretary shall mail a notice to the last known address of each member of the last House of Delegates at least twenty days before such special session is to be held, in which notice shall be specified the time and place of meeting, and the object of such special session. No other business shall be transacted at the special session than that specified in the call.

Chapter VII.—Nomination, Election and Installation of Officers, Trustees, Associate and Honorary Members

Section 1. Nominations.—Nominations for office shall be made orally; a nominating speech must not exceed two minutes. The treasurer shall be nominated by the Board of Trustees.

Sec. 2. Method of Holding Elections.—All elections shall be by ballot and a majority of the votes cast shall be necessary to elect. In case no nominee receives a majority of the votes on the first ballot the nominee receiving the lowest number of the votes shall be dropped and a new ballot taken. This procedure shall be continued until one of the nominees receives a majority of all the votes cast, when he shall be declared elected.

Sec. 4. Associate and Honorary Members.—Applications for associate membership from foreign physicians must be approved by the Judicial Council, applications from dentists must be approved by the Section on Stomatology, and from pharmacists by the Section on Pharmacology and Therapeutics.

Nominations for honorary membership shall be made by the Sections and must be submitted to the House of Delegates not later than the second day of the annual session. These applications and nominations shall be referred without debate to the Committee on Sections and Section Work, which shall consider the scientific attainments and professional character of the applicants and report to the House of Delegates.

The election of associate and honorary members shall immediately follow the election of officers. Not more than three honorary members shall be elected in any one year.

Sec. 5. Installation.—The general officers of the Association, except the President, shall assume their duties at the close of the last meeting of the annual session at which they are elected.

Chapter VIII.—Duties of Officers

Section 1. President.—The President shall preside at the General Meeting and at the meetings of the House of Delegates, and shall perform such duties as custom and parliamentary usage require. On the morning of the first day of the annual session following his election he shall deliver an address at the General Meeting on such matters as he may deem of importance to the Association. He may at any time make suggestions in writing to the House of Delegates or to any special or standing committee.

Sec. 3. Secretary.—The Secretary shall give due notice of the time and place of all annual and special sessions of the Association and of the House of Delegates in The Journal of the American Medical Association. He shall send an official notice of each annual or special session to the secretary of each constituent association and to the secretary of each section. He shall keep the minutes of the House of Delegates. He shall notify members of committees of their appointment and of the duties assigned to them. He shall verify the credentials of the members of the House of Delegates and shall provide a registration book in which shall be recorded the name of each delegate in attendance at each session, together with that of the Association, government service or Section which he represents. He shall prepare a roll of the delegates attending each session to facilitate voting by roll-call. He shall prepare for publication the official program of each session, and shall perform such other duties as may be directed by the House of Delegates or the board of trustees.

Chapter X.

Section 1. Classification of Committees.—Committees shall be classified as (a) Standing Committee. (b) Reference Committee, and (c) Special Committee. These Committees shall be nominated by the President and elected by the House of Delegates unless otherwise provided for in these by-laws. Any of these committees acting during the interval between the sessions of the House of Delegates shall be subject to the Board of Trustees. In case of vacancies in Committees occurring during the interval between annual sessions the president shall have the power to appoint members to fill the vacancies until the next annual session.

Sec. 2. Membership of Committees.—Reference Committees shall be appointed by the President from among the House of Delegates. et' seq.

Sec. 3. Standing Committees.—Amend to read as follows: Standing committees shall be the following:

(a) Committee (or Council) on Medical Legislation.
(b) Council on Medical Education.
(c) Committee on Transportation and Place of Session.

Sec. 4. Judicial Council.—Amend to read as follows: The Judicial Council shall be composed of five members, to be appointed by the President on the first day of each annual session from the delegates present, and to continue in office until their successors are appointed. It shall organize by electing a chairman and a secretary, who shall keep a permanent record of its proceedings. The council shall hold such meetings during the annual session and during the year as it may deem necessary. It shall make an annual report of its proceedings to the House of Delegates. To this council shall be referred all applications for associate membership from physicians resident in foreign countries and all questions, complaints, protests and matters of an ethical nature. When these concern an individual's relations with his local society, they shall be considered by this council only after the same shall have been referred to the Constituent Association concerned or on an appeal from such Constituent Association. Its decisions shall be subject to appeal to the House of Delegates.

Sec. 5. Committee on Medical Legislation.—Amend to read as follows:

There shall be a Council on Health and Public Instruction to consist of five members, to be elected by the House of Delegates, on nomination by the President. Those first elected shall serve, one for one year, one for two years, one for three years, one for four years and one for five years, and their respective terms of service shall be determined by lot. Thereafter one member shall be elected annually, on nomination by the President, to serve five years. The Council shall organize and shall elect a chairman from its number. The Board of Trustees shall appoint a secretary on nomination by the Council, and shall fix his salary.

The Council shall adopt such rules and regulations for the government of its actions as it may deem expedient. It shall expend money or contract financial obligations only as shall be authorized in writing by the Board of Trustees. The work of the Council shall embrace the following subjects:

(a) Legislation; (b) Organization; (c) Publicity; (d) Defense of Medical Research; (e) Public Health.

It may appoint committees to carry on the respective purposes of the Council. It shall make an annual report of its work to the House of Delegates. The office of the Council shall be at the headquarters of the Association.

Sec. 6.—Committee on Transportation and Place of Session to remain unchanged.

Sec. 8. Reports of Standing Committees.—Reports of Standing Committees, so far as possible, shall be transmitted 30 days before the annual session to the Secretary, who shall have them printed for distribution to the members of the House of Delegates.

Present Section 10 to become Section 9 and to be amended to read: These committees shall serve during the session at which they are appointed.

Chapter XII.—Sections

Section 2, page 26.—Officers of Sections.—The third sentence to be amended to read as follows: Each Section shall also elect annually one delegate and one alternate to the House of Delegates of the American Medical Association to serve one year.

Sec. 3, page 27.—Election of Officers.—The first sentence to be amended to read as follows: The election of officers shall be the first order of business of the morning meeting of the Section on the third day of each annual session.

Sec. 5, page 28.—Executive Committee.—Second and third sentences to read: In case of absence of a member of the Executive Committee from an annual session, the vacancy shall be filled by the chairman. The committee shall examine and pass on all papers, etc.

Sec. 6.—Meetings.—Strike out everything after the word "decide."

Sec. 7.—Who May Take Part in Section Work.—Members and associate members only shall have the right to participate in the business deliberations of a Section. Members and associate and honorary members and invited guests may present papers and take part in the scientific discussions.

Sec. 9, page 29.—Times at Which Titles Must Be In.—Titles of papers to be presented to the section must be in the hands of the secretary of the section at least thirty-five days before the first day of the annual session. With the title, the writer shall submit an abstract of the paper not less than thirty or more than one hundred and fifty words in length and an estimate of the time required to read his paper.

Sec. 12.—Can Present Papers Before Only Two Sections.—Amend to read as follows: No member shall present a paper or papers before more than two sections at any annual session. When more than one section is to be addressed, the titles and abstracts of both papers must be submitted to the secretaries of both sections before which the papers are to be read.

Chapter XIII.—Publication

Section 2.—Papers Must Be Ready for Publication.—Page 30 to read as follows: Each author shall hand his paper to the secretary of the section immediately after it is read. The secretary shall endorse thereon that it has been read and shall hand it to the chairman of the executive committee. All papers approved by the executive committee shall be returned to the secretary of the section, who shall at once forward them to the editor of The Journal.

Amendments to the Constitution

In view of the fact that the amendments are important and that the laws of the State of Illinois provide that any constitution of an incorporated body may be amended at any annual session of that organization, the committee recommend the unanimous consent and the adoption of the following changes in the constitution:

Article 5.—House of Delegates

Second sentence to be amended to read as follows: It shall consist of delegates elected by the constituent associations and by the scientific sessions of the American Medical Association, and appointed by the surgeon generals from the medical departments of the Army, Navy and the United States Public Health and Marine-Hospital Service, etc.

Article 8.—Annual Sessions

The Association shall hold an annual session at a time and place to be fixed by the House of Delegates. The time and place of session may, however, be changed by the unanimous action of the Board of Trustees at any time prior to two months of the time selected for the session. The annual session may be held at any place in the United States.

Article 12.—Amendments

Amend to read:

The House of Delegates may amend any article of this constitution at any annual session, provided that the proposed amendment shall not be acted on until the next annual session following that at which it was introduced and providing that three-fourths of the voting members of the House of Delegates registered at the session at which action is taken vote in favor of such change or amendment.

UNIFORM MEMBERSHIP

Of the recommendations submitted in the report of the Committee on Uniform Regulation of Membership, the Reference Committee recommends the following substitute for your adoption:

Resolved, That the report submitted by the above Committee on Uniform Regulation of Membership be referred to the Council on Health and Publicity with the request that these recommendations be submitted to the secretary at each constituent association for criticisms and suggestions and that the Council be requested to report on this subject at the 1911 session. The Reference Committee further recommends that the secretary send a certified copy of the constitution and by-laws of the American Medical Association as amended at this session to the secretary of each constituent association with the request that the changes be brought to the attention of the House of Delegates of the constituent Association.

The Reference Committee recommends that the resolution presented in the name of the Medical Association of the State of Alabama be referred to the Council on Health and Public Instruction for the consideration which the importance of the resolution demands.

The Reference Committee recommends that the word "general" be stricken out throughout the by-laws—when followed by secretary.

A. R. CRAIG, Chairman.

Dr. W. C. Woodward, District of Columbia, moved that the report of this committee, so far as it undertakes to alter the constitution and by-laws, be printed or mimeographed alongside of the sections which it proposes to alter, and distributed among the members of the House of Delegates for consideration on Thursday.

Seconded and carried.

Dr. Edwin Walker, Indiana, moved that the consideration of the constitution and by-laws be fixed for 10 a. m. Thursday.

Seconded.

Dr. E. J. McKnight, Connecticut, moved to amend that it be made a special order for 10 a. m. Thursday.

The amendment was seconded, accepted, and the original motion, as amended, was carried.

Resolution on Organization

Dr. Hubert Work, Colorado, presented the following:

WHEREAS, The plan of organization of the profession carried to its logical conclusion means that every member of a county society should be *ipso facto* a member of the American Medical Association, just as every member of a county society is *ipso facto* a member of a state society, and as it is the ultimate end of the plan that the American Medical Association should be coextensive with the organized profession throughout the land as nearly, if not quite, every state already has adopted the plan so far as making every member of a county society a member of a state society; therefore, be it

Resolved, That the President appoint a committee to draw up details for extending the plan to the American Medical Association, and to present this plan to the various state societies for their consideration during the coming year, and to make a report at the next annual meeting of this House.

Dr. Work moved the adoption of the resolution. Seconded.

Dr. Alexander Lambert, New York, moved as an amendment that this resolution be referred to the 'Board of Trustees because it means a separation of THE JOURNAL from the membership in a manner which involves the finances of the Association.

The amendment was seconded, accepted, and the original motion, as amended, was carried.

Report on Legislation Concerning the Sale of Habit-Forming Drugs

Dr. C. S. N. Hallberg, Illinois, presented the following report from the Section on Pharmacology and Therapeutics:

To the Members of the House of Delegates of the American Medical Association:

A resolution introduced by Mr. M. I. Wilbert at the Atlantic City session to the effect that this section request the House of Delegates to recommend to the United States government the passage of a law whi h should place the sale of certain habit-forming drugs under the control of the Department of Internal Revenue was referı d for consideration to the executive committee of this sectioı Within the past few months a bill has been introduced into the Senate by Mr. Cullom which has an object similar to that desired by Mr. Wilbert. Your committee has carefully studied this bill, and while in a general way they approve of the plan of regulating the sale of these drugs by some sort of federal license, there are a number of features in the Cullom bill which seem to the committee to be objectionable. For instance, there is a uniform tax of a dollar a pound on all substances included under the bill equally for cocain and for coca leaves and for morphin and for crude opium. As cocain is almost one hundred times as costly as coca leaves it is evident that a uniform tax would work a hardship on American manufacturers of the alkaloids and would almost exclude the importation of these crude drugs in favor of the alkaloidal principles.

Whether or not these objections could be obviated by amendments to the bill, the committee is uncertain. The whole subject is so extraordinarily complex that the commitee does not feel justified in making definite statements concerning the subject. We do not, therefore, recommend that the section take any definite action concerning this bill. We feel that the question is one of such great importance, involving as it does not only the question of the physical welfare of a large proportion of the population, but also vast financial interests and complex legal questions that it seems to us very doubtful that any conclusion reached by a single section of the American Medical Association under the conditions which of necessity pertain to the section meetings would have any real value.

M. H. FUSSELL,
REID HUNT,
H. C. WOOD, JR.

Respectfully referred, through the House of Delegates, to the Committee on Medical Legislation, American Medical Association, by the Section on Pharmacology and Therapeutics.

MURRAY GALT MOTTER, Secretary.

On motion, the resolution was referred to the Reference Committee on Legislation and Political Action.

Resolution Regarding Branch Associations

Dr. S. S. Crockett, Tennessee, offered the following resolution:

Resolved, That our representatives to the House of Delegates of the American Medical Association be instructed to urge said House to endorse existing district associations as branches of the American Medical Association, namely, Southern Medical Association and the South Western Association as existing at present, and that other branches be created in other parts of the United States.

On motion, the resolution was referred to the Reference Committee on Miscellaneous Business.

Resolutions Regarding Publication of Suicides

Dr. J. H. White, Louisiana, presented the following resolutions from the Section on Preventive Medicine and Public Health:

According to the published reports of the Census Bureau, there has been of late a marked increase in the number of suicides in this country. The death-rate from this cause per 100,000 was as follows: 1902, 12.7; 1903, 13.9; 1904, 14.8; 1905, 16.1; 1906, 14.3; 1907, 16.2, and 1908, 18.5. An increase of practically 50 per cent. in seven years demands investigation and energetic action.

The publication in the secular papers of the details of these unfortunate occurrences can do no good. On the other hand, it is well recognized, by those in a position to judge, that such publication has powerful suggestive effect on susceptible individuals, and it is unquestionably one of the most active causes of this form of death; therefore, be it

Resolved, By the Section on Preventive Medicine and Public Health that such publication of accounts of suicides is detrimental to the good of the people of this country; and that we request the House of Delegates to take action in the case by requesting the press of the land to stop such publications; and

Further, That the House of Delegates be instructed to further the enactment of a national law forbidding the use of the mails by any paper making such publication; and

Further, That the same committee be instructed to assist in the passage of state laws making such publication a misdemeanor, and providing suitable punishment therefor.

Resolved, By the Section on Preventive Medicine and Public Health that such instruction by lectures or otherwise should be given in every such institution of learning; and

Resolved, That the House of Delegates be asked to appoint a committee to promote a course of instruction in all literary colleges and normal schools.

On motion, the resolutions were referred to the Reference Committee on Hygiene and Public Health.

Communication Regarding Dr. McCormack

Dr. W. E. Anderson, Virginia, read the following communication:

As a representative from Virginia to the American Medical Association, I want to call your attention to the excellent service rendered our state by Dr. J. N. McCormack in the addresses made by him last year. As you know, he spent two weeks with us and gave two talks a day, one to the physicians and one to the public. He never failed to elicit interest among the physicians in promoting more cordial relations among themselves and a higher standard of ethics and scientific medicine. In his talks to the public he always developed a greater appreciation of physicians and stimulated public health work. We hope to have Dr. McCormack for another two weeks in July.

I am mentioning this to you as Dr. McCormack came to Virginia as the official representative of the American Medical Association, and the occasion may arise in the House of Delegates for you to show an appreciation of him in behalf of this state.

With kind regards, I am, very truly yours,

Ennion G. Williams,
Commissioner of Health.

Dr. Anderson said further: "Commenting on this communication, I recall with pleasure the remarks made in the House of Delegates at Portland, Ore., meeting of this Association, commending Dr. McCormack's work, speaking of the influence of continuing the same, inviting him to visit Virginia. He has twice since done this, with the splendid results mentioned in this letter. Virginia appreciates Dr. McCormack and his work, and on behalf of our delegation I respectfully request this body to let the good work go on."

There being no objection, this communication was referred to the Reference Committee on Reports of Officers.

On motion, the House of Delegates then adjourned until 10 a. m. Thursday.

Fifth Meeting — Thursday Morning, June 9

The House of Delegates met at 10 a. m., and was called to order by Third Vice-President Dr. Alexander Lambert, New York. The secretary called the roll.

The minutes of the previous meeting were read and approved.

Discussion of Amendments to Constitution and By-Laws

The Chairman stated that the special order at this time was the consideration of amendments to the Constitution and By-Laws.

Dr. T. A. Woodruff, Illinois, moved that the proposed amendments to the Constitution and By-Laws, excepting the amendment relating to the organization of the Council on Public Health and Public Instruction, to be deferred until next year, and that the Secretary be instructed to have the proposed amendments printed and distributed to the members of the House of Delegates for consideration in the meantime, and that we now proceed to take up the amendments with regard to the organization of the Council on Health and Public Instruction.

This motion was seconded by several, and after discussion by Drs. Alexander R. Craig, Pennsylvania; Charles S. Bacon, Illinois, Dr. Bacon moved that the motion of Dr. Woodruff be laid on the table. Seconded and carried.

Dr. A. T. McCormack, Kentucky, moved that Sections making changes be considered *seriatim*. Seconded and carried.

Dr. George W. Guthrie, Pennsylvania, moved the adoption f the report of the Reference Committee on Amendments to Constitution and By-Laws as a whole.

is motion was seconded by several, and after discussion s. C. E. Cantrell, Texas; E. T. Abrams, Michigan; Ed- Jackson, Colorado; Dr. Charles Chassaignac, Louisiana, that the motion of Dr. Guthrie be laid on the table. otion was seconded, but declared lost.

Dr. Chassaignac protested against such action by the House of Delegates, and thought the report ought to be read and carefully considered before adopting it as a whole.

Dr. A. T. McCormack, Kentucky, asked unanimous consent of the House of Delegates that the report be read as a whole, and as this was given, the report was read.

At the conclusion of the reading of the report, Dr. Charles S. Bacon, Illinois, raised the point of order that it was not proper for the House of Delegates to adopt this report as a whole if it meant the adoption of all the amendments to the Constitution and By-Laws. He said that the Constitution provides that amendments to the Constitution and By-Laws shall be adopted by a three-fourths vote of all members, and this could not be determined by simply adopting the report of the committee; therefore, he held that the motion to adopt the report as a whole was not a proper one.

The Chair sustained the point of order.

Dr. Alexander R. Craig, Pennsylvania, said: The committee asked for unanimous consent to permit action on the amendments to the articles of the Constitution, and this unanimous consent being denied, I move to amend Dr. Guthrie's motion to adopt the report as a whole, by taking action on all the report preceding the paragraphs referring to amendments to the Constitution.

This motion was seconded and accepted by Dr. Guthrie, and carried.

Dr. W. C. Woodward, District of Columbia, moved that the proposed amendments to Article IV of the Constitution as recommended by the committee be now adopted. Seconded and carried.

The President stated that the report of the Reference Committee on Amendments to the Constitution and By-Laws was still before the House and the substitute was now up for consideration.

Dr. A. T. McCormack, Kentucky, moved that the proposed amendments to the Constitution be laid over until next year. Seconded and carried.

Dr. McCormack asked further time for the consideration of the rest of the report, which was granted.

Dr. Charles S. Bacon, Illinois, asked unanimous consent that the By-Laws be amended to the effect that the Council on Pharmacy and Chemistry be added to the list of standing committees.

The Chair ruled that this amendment would be referred to the Reference Committee on Amendments to the Constitution and By-Laws.

On motion, the Association adjourned until 2 p. m.

Sixth Meeting — Thursday Afternoon, June 9

The House of Delegates met at 2 p. m. and was called to order by President Welch. The Secretary called the roll.

The minutes of the previous meeting were read, corrected, and approved.

Election of Officers

The election of officers being in order, the House of Delegates then proceeded with nominations for President.

Dr. Frank Billings, Illinois, nominated Dr. John B. Murphy, Chicago, for President.

This nomination was seconded by Drs. M. L. Harris, Illinois; Charles Chassaignac, Louisiana; T. A. Woodruff, Illinois, and C. E. Cantrell, Texas.

Dr. Edwin Walker, Indiana, nominated Dr. A. Jacobi, New York City, for President. The nomination of Dr. Jacobi was seconded by Dr. V. C. Pederson, New York City.

The President appointed as tellers Drs. J. Shelton Horsley, C. S. Bacon, A. T. McCormack, and I. C. Chase.

There were 115 votes cast, of which Dr. Murphy received 77, and Dr. Jacobi 38.

Dr. Murphy was declared elected President.

ELECTION OF VICE-PRESIDENTS

The following were then nominated and duly elected Vice-Presidents.

First Vice-President, Dr. E. E. Montgomery, Philadelphia, Pa.; second Vice-President, Dr. R. C. Coffey, Portland, Ore.; third Vice-President, Dr. W. G. Moore, St. Louis; fourth Vice-President, Dr. H. L. E. Johnson, Washington, D. C.

ELECTION OF SECRETARY

Dr. I. C. Chase, Texas: Gentlemen of the House of Delegates, I am not a stranger to organization work in this country. I have been secretary of one of the largest state associations, geographically, for a number of years. I come from a state where the opposition to organized medicine was probably greater than in any other one state in the Union, and that being the case, I may be said to represent, to a certain extent, the voice of the people. I believe that there is no particular reason why we should begin at this time to separate the offices of Editor and General Secretary of the American Medical Association. [Applause.] Those of you who are familiar with The Journal and the Association work are acquainted with the fact that there are great difficulties in the way of having two heads in the work of organization. It is not only not good reasoning but poor judgment at a critical time like this in this great association to change generals at the suggestion of the enemy. [Applause.] I know not what you may think, but I feel that we should not allow the howling coyotes among the enemies of this organization, to spread broadcast over this land the false report that they have urged and have secured changes in the American Medical Association through the character of literature they have distributed all over this country. [Loud applause.]

I take great pleasure, gentlemen of the House of Delegates, in nominating for secretary of the American Medical Association, a man who has never yet failed to sacrifice his own personal interests for the good of this great cause. [Applause.]

I therefore take great pleasure in nominating our former secretary, Dr. George H. Simmons. [Loud and prolonged applause.]

Dr. W. J. Birkofer, Nebraska: It gives me great pleasure to second the nomination of our former colleague from Nebraska, Dr. Simmons. [Applause.]

Dr. J. B. Bullitt, Mississippi: On behalf of the South, I wish to second the nomination of Dr. Simmons for secretary, a man who has done probably more for organization in this Association than any other one man in its ranks.

Dr. B. H. Blair, Ohio: Coming from a state which is perhaps the fourth largest representative state in the Union, whose profession has never faltered or failed, I desire to second the nomination of Dr. Simmons. [Applause.]

Dr. A. L. Wright, Iowa: Iowa unanimously seconds the nomination of Dr. Simmons. [Applause.]

Dr. Mack Rogers, Alabama: I would be derelict in my duty if I did not second this nomination on behalf of the state of Alabama.

Dr. A. R. Mitchell, Nebraska: I have been a fellow-citizen of Dr. Simmons for many years and during all those years and up to the present time there has never been a cloud on his character and as a representative from Nebraska, I take great pleasure in seconding the nomination of Dr. Simmons, and if it is in order I move that the rules of the House of Delegates be suspended and that the President cast a unanimous ballot of this House of Delegates for Dr. Simmons as secretary. [Applause.]

Dr. Stephen C. Glidden, Illinois: I wish to second the nomination of Dr. Simmons.

At this juncture, there were cries of "Speech! Speech!"

Dr. Simmons said: "I appreciate this honor, but I really believe it would be better for me not to accept this office. There is a great deal of responsibility connected with it, and I have realized in the last three or four years that we are not making as much progress in organization work as we should make. I, myself, think that new blood is needed. We are all liable to get into ruts and I am afraid I have gotten into a rut. Nevertheless, after this expression of your appreciation, I will say this, that while personally my own feeling is that I should not accept the position, if you insist that I should fill the office another year, I will do it. [Applause.] I believe, however, that it would be better for the House to select some one else."

Dr. J. A. Walker, Oklahoma: You have heard representatives of the old states, but I represent a new state. This is a matter in which I believe Dr. Simmons has no say. We are running this. [Laughter.] I think team work is very important, and I look on Dr. McCormack as our pitcher and on Dr. Simmons as our catcher. They have done excellent team work. They have won out. [Applause.] Dr. Simmons is in error when he said that not as much progress has been made in organization work as there ought to have been made. Of course, he has not been in Oklahoma. We have invited him to visit us and I wish to say to you that we have made great advancement in medical organization under Dr. McCormack. [Applause.]

We had the pleasure of having Dr. McCormack with us three times and he has revolutionized the practice of medicine in Oklahoma and medical organization, and I believe we are as well organized in that state and are working in as perfect order as they are anywhere in the United States, not excepting Illinois, Indiana, or any other state, and I rise in behalf of Oklahoma to second the nomination of Dr. Simmons. I also wish to extend to the man from Texas, my native home, the hand of fellowship for nominating Dr. Simmons.

Dr. C. E. Cantrell, Texas: On behalf of the delegates of this House, I move we all nominate Dr. Simmons by a rising vote.

It was then moved that nominations be closed and the President be instructed to cast the ballot of the House of Delegates for Dr. Geo. H. Simmons as secretary.

This motion was seconded by several and was carried unanimously.

The President said he took great pleasure in casting the ballot and announcing that Dr. Simmons had been unanimously elected Secretary of the Association. [Loud Applause.]

There were cries of "Speech! Speech!"

Dr. Simmons said: I do not know that I am in a condition to speak. I thoroughly meant what I said in my report. I also meant what I said a few moments ago, that I was ready to step to the front, and especially so long as I realized that there are around me and back of me the best element of the medical profession of this country. [Applause.]

In thanking you, I can only say that I will do the best I can in the future as I have done in the past. [Applause.]

ELECTION OF TREASURER

Nominations for treasurer being in order, Dr. M. L. Harris, for the Board of Trustees, nominated Dr. Frank Billings.

The nomination was seconded by Dr. T. D. Coleman, Georgia.

There being no other nominations, Dr. Alexander R. Craig, Pennsylvania, moved that the rules be suspended and the Secretary be instructed to cast the ballot of the House for Dr. Billings as treasurer.

This motion was seconded by several, and carried. The Secretary cast the ballot and Dr. Billings was declared duly elected treasurer of the Association.

TRUSTEES ELECTED

The following trustees were then elected:

Trustees.—Dr. W. W. Grant, Denver; Dr. Frank J. Lutz, St. Louis; Dr. C. E. Cantrell, Greenville, Texas.

COMMITTEES APPOINTED

The President then made the following appointments, which were confirmed by the House of Delegates:

Council on Medical Education.—Dr. George Dock, St. Louis, to succeed Dr. E. E. Southard, Boston, to serve until 1915.

Council on Health and Public Instruction.—Dr. H. M. Bracken, Minneapolis, to represent public health; Dr. W. B. Cannon, Boston, to represent defense of medical research; Dr. Henry B. Favill, Chicago, to represent public instruction; Dr. J. N. McCormack, Bowling Green, to represent organization, and Dr. W. C. Woodward, Washington, D. C., to represent legislation.

Report of the Reference Committee on Sections and Section Work

Under this head Dr. J. E. Weeks, New York, Chairman, read the following report of the Reference Committee on Sections and Section Work:

To the Members of the House of Delegates of the American Medical Association:

ELECTION OF HONORARY AND ASSOCIATE MEMBERS

The Reference Committee on Sections and Section Work, to which was referred the recommendation of the Section on Nervous and Mental Diseases that Dr. Alfred Saenger, of Hamburg, Germany, be elected an honorary member of this Association; the recommendation of the Section on Ophthalmology that Mr. J. Herbert Parsons, F.R.C.S., be elected an honorary member of this Association; also the nomination by Dr. Frank Billings of Dr. James H. Honan, of Berlin, Germany, for election to honorary membership in this Association, desires to report favorably in regard to these recommendations.

J. E. WEEKS, Chairman.

On motion of Dr. A. T. McCormack, Kentucky, the Secretary was instructed to cast the ballot of the House for the election of these honorary members, which he did, and they were declared duly elected.

Dr. Graham Lusk, New York City, was nominated for associate membership by the Section on Pathology and Physiology, and on motion, the nomination was confirmed.

A report from the Section on Stomatology was read, recommending that the following gentlemen be made associate members:

L. P. BETHEL, Columbus, Ohio.
S. S. CHILCOTT, Bangor, Maine.
H. LOGAN GEARY, Seattle, Wash.
F. W. STIFF, Richmond, Va.
J. P. GRAY, Nashville, Tenn.
H. F. CASSEL, St. Louis.

On motion, the recommendation was concurred in.

Resolutions on Sex-Hygiene

By unanimous consent of the House, Dr. Thomas D. Davis, Pennsylvania, presented the following preamble and resolution, from the American Federation for Sex-Hygiene, with the request for their formal adoption. They were referred to the Council on Health and Public Instruction.

WHEREAS, The necessity daily appears more imperative of protecting innocent American women and children against infection by the social diseases, syphilis and gonorrhea; and

WHEREAS, There is ample evidence of a belief deeply grounded among the laity that sexual indulgence is necessary to the health of the normal man; and

WHEREAS, There exist, in consequence, widely differing and double standards of morals and of physical health for the male and female sexes, that lead directly to the disease and death of many of our women and children; be it

Resolved, That the American Medical Association, through its House of Delegates, hereby presents for the instruction and protection of the lay public the unqualified declaration that illicit sexual intercourse is not only unnecessary to health, but that its direct consequences in terms of infectious disease constitute a grave menace to the physical integrity of the individual and of the nation.

ROBERT N. WILLSON, Secretary Pro Tem.

Report of the Board of Trustees

Dr. M. L. Harris, Chairman of the Board of Trustees, presented the following report:

To the Members of the House of Delegates of the American Medical Association:

The Board of Trustees respectfully returns to the House of Delegates the report of the Committee on Davis Memorial, which was referred to it, for the reason that the committee is a committee of the House of Delegates, and the Board of Trustees has no power to accept resignations of its members, nor to fill vacancies.

M. L. HARRIS, Chairman.

On motion of Dr. Edward Jackson, Colorado, the resignations of the Chairman and Treasurer of the Davis Memorial Committee were accepted, and the President instructed to appoint their successors.

Special Journals to Be Established

Dr. Harris, speaking for the Board of Trustees, said that as is known, there is published at THE JOURNAL office the *Archives of Internal Medicine.* This was done at the request and petition of members of the Section on Practice of Medicine of the American Medical Association, and the Board of Trustees had been petitioned by two other sections to publish similar journals for their benefit, namely, a journal devoted to surgery and a journal devoted to pediatrics. While the Board of Trustees has full authority under the By-Laws to do this, the board would like the approval of the House of Delegates before undertaking the extension of this work. These journals would not interfere in any way with THE JOURNAL of the American Medical Association. They would be journals of an entirely different character. These journals would not be issued immediately, but, as soon as the Association had facilities in its new building, the matter would be taken up.

Dr. Frank Billings, Illinois, moved that the Board of Trustees be empowered, as soon as the printing facilities of the Association would permit, to publish these two special journals.

This motion was seconded by several.

Dr. Edwin Walker, Indiana, moved to amend by adding the words, "provided there shall be no expense to the Association."

The amendment was seconded and accepted.

Dr. C. E. Cantrell, Texas, speaking for the Board of Trustees, said it looked as though these journals would be self-sustaining, and he did not think the House of Delegates should bind the Board of Trustees too closely in beginning the publication of such journals.

Dr. Edwin Walker, Indiana, did not think the Board of Trustees should go into a publishing enterprise which might cause the Association to lose money.

Dr. J. Riddle Goffe, New York City, agreed with Dr. Walker, and said he had found from his experience in medical journalism that medical journals did not pay very well. He thought the Board of Trustees, before entering into such an arrangement, should be guaranteed by the Sections against loss from the publication of these journals.

Dr. M. L. Harris, Illinois, said the Association had not lost anything yet. One of the objects of the Association was to publish things which were for the benefit of the profession, and the Board of Trustees had been asked to do this for the benefit of the profession.

Dr. Mack Rogers, Alabama, asked whether the publication of the *Archives of Internal Medicine* had been a success.

Dr. Harris replied that it had been successful in every way.

Dr. A. T. McCormack, Kentucky, said he had had some experience in medical journalism recently, and those who had been engaged in the practice of medicine for a long time had realized for many years, owing to the varied character of the advertisements carried by most medical journals, and the dangerous character of the advertisers, that financial losses were frequent, because the profession failed to support and appreciate those journals. In recent years many medical journals had not carried those advertisements. These two proposed journals would carry none, and every physician interested in surgery or pediatrics could no more fail to have such journals in their offices than men who were engaged in original research would fail to take the *Archives of Internal Medicine.* For this reason the Board of Trustees should be empowered to publish such medical journals without advertising, if they saw fit to do so. He favored the publication of clean cut, scientific journals of the class under consideration.

Dr. C. R. Woodson, Missouri, then moved as a substitute that the matter be referred to the Board of Trustees, with full power to act.

Seconded.

The President asked Dr. Simmons to speak on the subject. Dr. Simmons said: "There is nothing we can spend our money for to better advantage, if it is necessary, than in putting out the class of literature that is intended by the publication of the two journals mentioned. Those of you who take the *Archives of Internal Medicine* realize that it publishes a class of literature that no private publisher would think of undertaking in the form in which it is published. The Association has now a splendid printing plant and is able to do that work much cheaper than any private publisher could think of doing it. These two proposed journals, one devoted to surgery, and the other to pediatrics, would be high-class in every way. The argument is made that there are no journals, such as the German journals, in the English language that can be regarded as high-class which will publish long and exhaustive scientific articles devoted exclusively to surgical and pediatric subjects. I believe we can do nothing that will help scientific medicine in this country so much as the publication of high-class scientific journals that private publishers cannot publish, even though it may be done at a loss. It is not fair to say that the Trustees shall not start those journals unless they succeed. They will not succeed financially the first few months, and cannot possibly succeed unless payments are demanded in advance and are guaranteed. You cannot expect these journals to pay for the first year, but there is nothing which will help scientific medicine more than the publication of such journals as have been mentioned.

Dr. Edwin Walker withdrew his amendment with the consent of the seconder.

Dr. Woodson then renewed his motion, which was put and carried.

Selection of Los Angeles as Next Meeting Place

Dr. I. C. Chase, Texas, moved that the regular order of business be set aside, and that the House of Delegates proceed immediately to consider the place of meeting for next year.

Seconded and carried unanimously.

Dr. M. L. Harris, Chairman of the Committee on Transportation and Place of Session, said the Committee had received invitations from Atlantic City, N. J.; Chattanooga, Tenn.; Buffalo, N. Y.; Los Angeles, California, and Louisville, Ky., but as there was not a majority of the members of the Committee present, the members present were not able to make any recommendation as to the next place of session, and thought it would be best for the House to decide.

Dr. Alexander R. Craig, Pennsylvania, moved that Los Angeles and Buffalo be placed in nomination, and a ballot taken.

Seconded and carried.

There were 119 votes cast, and of this number Los Angeles received 61, and Buffalo 58.

Los Angeles was declared to be the next place of session.

Report of the Reference Committee on Amendments to the Constitution and By-Laws

Dr. Alexander R. Craig, Pennsylvania, Chairman, presented the following report of the Reference Committee on Amendments to the Constitution and By-Laws:

The Reference Committee on Constitution and By-Laws begs leave to submit the following supplementary report:

Since the presentation of its former report, the Committee has received the advice that the suggestion of the establishment of the Committee on Uniform Regulation of Membership originated with the Association of State Secretaries and Editors.

The Reference Committee, therefore, recommend that the Council on Health and Public Instruction be requested to continue the Committee, with such changes in its personnel as will fill the Committee with secretaries of constituent associations.

The Reference Committee considered the resolution offered by Dr. Dowling:

WHEREAS, There are old and distinguished doctors in various
states whose careers have adorned the profession;
Resolved, That those who have been elected to honorary mem-
bership in the component state association shall be entitled to mem-
bership (hon--ry) in this Association on recommendation of the
hous-rns junctus of the component state association, bearing the
president and secretary and the seal of the state
Dr. Simmons s--d the said doctor is a member of the Association

as we should make. I, mmends that authority be given the
We are all liable to get in nce Committee to renumber chapters
into a rut. Nevertheless, aws. as amended, should that prove
ciation, I will say this, tha t any grammatical or typographic

The Committee further recommends that Article 9, of the Constitution, be amended by striking out of Section 1 "and a treasurer." This amendment awaits the action of the House at the next annual session.

The Committee recommends that the House reconsider the action of this morning, in so far as to enable the change of the title of the Council on Health and Publicity to the title of the Council on Health and Public Instruction.

A. R. CRAIG, Chairman.

On motion, the report was adopted.

Report of the Reference Committee on Reports of Officers

Dr. George W. Guthrie, Pennsylvania, Chairman of the Reference Committee on Reports of Officers, presented the following report:

Your Committee, to which was referred the communication of Dr. Williams, beg to report that commendation of the work of Dr. McCormack was embraced in a previous report of the Committee, advising that the good work go on.

GEORGE W. GUTHRIE, Chairman.

The President stated that no action was necessary on this report.

Report of the Reference Committee on Hygiene and Public Health

Dr. C. S. Sheldon, a member of the Reference Committee on Hygiene and Public Health, read the following report:

To the Members of the House of Delegates of the American Medical Association:

OPTOMETRY DEPRECATED

The Reference Committee on Hygiene and Public Health, to which was referred a recommendation of the Optometry Committee of the Section on Ophthalmology, of last year, which resolutions deprecate the multiplication of optometry boards in the different states, and the appointment of non-medical and unqualified persons thereon, and which resolution further recommends the publication of the history of so-called optometry and optometry colleges, and the dissemination of such information, in regard to these so-called optometry colleges, and especially the furnishing of such information to medical societies and state medical boards, advise that these be approved.

FORM COMMITTEE ON PREVENTION OF BLINDNESS

The Reference Committee on Hygiene and Public Health, to which was referred a resolution of the Section on Ophthalmology, recommending the appointment of a "Committee on the Prevention of Blindness," recommends that the name of the present Committee on Ophthalmia Neonatorum be changed to that of the Committee on the Prevention of Blindness; and that the scope of said committee's work be correspondingly enlarged.

DISCOURAGE SUICIDE PUBLICITY

The Reference Committee on Hygiene and Public Health, to which was referred the resolution of the Section on Preventive Medicine and Public Health, in reference to publication by newspapers of the details of suicide, begs to report that the recommendation contained in the resolution seems, in some respects, inadvisable, at this time, and your Committee recommends the following resolution as a substitute:

Resolved, That it is the sense of the House of Delegates of the American Medical Association that the publication of the details of suicide by newspapers is one of the potent causes of other suicides by the suggestive influence of such published details; and it is, therefore, recommended to the public press that the details of suicide be omitted from publication.

The Reference Committee on Hygiene and Public Health, to which was referred the resolution of the Section on Preventive Medicine and Public Health, which recommends the appointment of a committee to promote instruction in all literary colleges and normal schools on matters of public health, begs to commend the purpose of this resolution, and to recommend that it be referred to the Council on Health and Public Instruction.

VISUAL STANDARDS ADVISED

The Reference Committee on Hygiene and Public Health, to which was referred the resolution of this Section on Ophthalmology, which recommends that the American Medical Association, through its President, shall appoint a committee to confer with the Department of Commerce and Labor, and with the Marine Hospital Service, with a view of "establishing proper visual standards and tests to govern these public servants," recommends that the resolution be approved.

The Reference Committee on Hygiene and Public Health, to which was referred the recommendation of the Section on Ophthalmology for 1909, in reference to the formulation of a curriculum to better equip medical students and practitioners with a knowledge of "infectious diseases of the eye and its refractive defects," respectfully recommend the consideration of the work contemplated by this resolution be referred to the Council on Health and Public Instruction.

Respectfully submitted.
William N. Wishard, Chairman.

On motion the report was adopted.

Report of the Reference Committee on Miscellaneous Business

The following report was presented:

To the Members of the House of Delegates of the American Medical Association:

The Reference Committee on Miscellaneous Business, to which was referred the resolution from Dr. S. S. Crockett, of Tennessee, asking endorsement of the Southern Medical Association as a branch of the American Medical Association, begs to report that while the committee is in sympathy with the request, we suggest, because sufficient data did not accompany the resolution, that this matter be deferred until a more formal application be presented, accompanied by the constitution and by-laws of the petitioning society.

Respectfully submitted.
T. A. Woodruff, Chairman.
Edwin Walker,
Ridgely B. Warfield,
E. A. Hines,
E. J. Goodwin.

On motion, the report was adopted.

Report of Reference Committee on Legislation and Political Action

Dr. J. W. Clemmer, Ohio, Chairman of the Reference Committee on Legislation and Political Action, reported that only one item had been referred to the Committee, and this related to legislation on habit-forming drugs. This is a very important matter, requiring a great deal of time, attention and technical information. For this reason, the Committee recommended that the matter be submitted to the Council on Health and Public Instruction.

On motion, the report was adopted.

Expressions of Thanks

Dr. Hubert Work, Colorado, introduced the following:

The House of Delegates, in behalf of the American Medical Association, desires to express its cordial appreciation and thanks to the Missouri State Medical Society for its hospitality and the cordial welcome extended to the Association in the masterful address of its President and to Dr. Moore;

To His Excellency, Governor Hadley, for his scholarly address, in which he showed himself conversant with and appreciative of the aims, desires and purposes of twentieth century medicine;

To Dr. Dorsett and his Committee on Arrangements;

To Mayor Kreismann for his official courtesies;

To the Committee on Ladies' Entertainment, which contributed so intelligently to the enjoyment of our lady guests;

To the press of the city and thousands of others who have contributed their quota toward the sum total of our happiness while guests in this city.

St. Louis has again demonstrated her world-wide reputation for hospitality to the stranger-guest, a reputation which was established beyond dispute at her World's Fair a few years since.

To the retiring officers of this Association the thanks of the House of Delegates are especially tendered. Their services have been intelligent, earnest, and at all times loyal to the best interests of the Association, to public health and to the elevation of scientific medicine.

This was unanimously adopted by a rising vote.

Dr. Alexander R. Craig moved that a vote of thanks be extended not only to the retiring officers, but to the officers who had conducted the meetings of the House of Delegates with so much impartiality and decorum. Seconded and carried.

Dr. H. G. Wetherill, Colorado, moved that a rising vote of thanks be extended to Dr. W. B. Dorsett, Chairman of the Local Committee on Arrangements. Seconded and carried unanimously.

Dr. Dorsett thanked the members of the House of Delegates for their words of praise and vote of appreciation.

As there was no further business to come before the meeting, on motion, the House of Delegates adjourned *sine die*.

Addenda

The following reports of committees and officers were omitted because of limitations of space in The Journal, June 11, 1910, pages 1979, 1986, etc., from the report of the second meeting, Monday afternoon, June 6.

Report of the Board of Public Instruction on Medical Subjects

To the Members of the House of Delegates of the American Medical Association:

The report of the Board of Public Instruction is brief. Plans for the systematic institution of a progressive scheme of instruction on topics relating to public health have been held in abeyance until the report is before you of a Committee on the Organization of a Council on Public Health, Publicity and Legislation under the chairmanship of Dr. C. A. L. Reed. The report of this committee will deal with the centralization and coordination of several committees under a specially organized council, which will eliminate the duplication of activities along similar lines as well as greatly reducing the expenditures for this work. The Board of Public Instruction on medical subjects also feels that a central bureau should be a constituent part of the central administration offices of the American Medical Association. From this center matters of great public interest could be disseminated. This board therefore, heartily concurs with the concentration plan to be suggested by the committee under the chairmanship of Dr. Reed.

In deference to the wishes of the Board of Trustees the work of the Board of Public Instruction on Medical Subjects has been held under advisement until this concentration plan shall have been considered and acted on by the House of Delegates. For this reason our program for the past year has been abbreviated. Two popular articles have been prepared and are now in press, one on "The Venereal Peril," the other on "Typhoid Fever." We are pleased to note, however, that there has been a general and most creditable endeavor on the part of several committees appointed by the House of Delegates, as well as that of the state organizations, to place before the lay world many topics of great educational value. Also many timely articles have appeared in the current magazines which have created widespread interest, and in one instance at least a large endowment was created for the study of hookworm disease, thus popularly exploited. Unfortunately, much of the initiative in the great progressive health movements has come from the lay public, the physician occupying the position of an aid rather than an originator.

The recent tendencies, however, for physicians to participate, within ethical bounds, in matters of public interest has been most creditable and we believe that a most optimistic forecast is justifiable as to the progress of this work. Careful organization and systematic endeavor are necessary to bring it to the best issue. Respectfully submitted.

John G. Clark, Chairman.

Report of the Committee on Nomenclature and Classification of Diseases

To the Members of the House of Delegates of the American Medical Association:

Your Committee on Nomenclature and Classification of Diseases beg leave to submit the following report, which, it must be confessed, is hardly more than a report of progress. It seems impossible to do more at present, for at the time of our last report we had reached a point in our work where it was necessary to wait for the revision of the International Classification of Causes of Death. It was confidently expected that the French version would reach the Bureau of the Census last October, but it was not received there until some time in January. Dr. Wilbur, the bureau's chief statistician for vital statistics, at once began the labor of translation, but he encountered points of uncertainty which made it necessary for him to correspond with M. Bertillon; hence further delay. It was not until April 21 that a copy of the translation was received by the undersigned, and it was incumbent on him to return that copy to Dr. Wilbur within a few days. Only during the week which is to end on May 7 did he obtain a copy that he could keep—manifestly too late for him to consult his colleagues with regard to it. This unfortunate delay is in no sense to be imputed to Dr. Wilbur, who, indeed, deserves the thanks of the profession for the excellence of the work which he has produced.

Your committee are more than ever inclined to recommend the adoption of the Bellevue Nomenclature. It was carefully revised about a year ago, and it is now again in process of revision, the numerals of the revised International Classification being assigned to its titles. A Latin list seems necessary in addition, and it is our opinion that, with very slight changes, the excellent list now employed by the Bureau of Medicine and Surgery of the Navy will supply that want. The adjustment, however, will require considerable work. In addition, a list of injuries according to their nature, regardless of the mode of their production (which is all that the International Classification takes cognizance of), will have to be prepared. Respectfully submitted,

Frank P. Foster, Chairman.

On motion, the report was referred to the Reference Committee on Miscellaneous Business.

Report of the Director of Post-Graduate Study

To the Members of the House of Delegates of the American Medical Association:

I herewith submit a report of the progress of the work of the course of post-graduate study for the year just closing.

On account of unavoidable delay on the part of the Director, the manuscript for the outline for the third year of the course was somewhat late in getting into the hands of the printer. But with the aid of the efficient assistant to the General Secretary, and of The Journal press, outlines were distributed to the waiting societies the latter part of September. Many of the societies that had taken the preceding year's course, as well as a large number of new societies, were ready to begin active work for the year.

Quite a number of societies begin the year's work the first of the calendar year, just after the election of officers. We noted at that time a rather marked increase in the demand for outlines, many of the new officers trying in this manner to arouse an interest and enthusiasm in their societies.

The Journal press printed two thousand outlines in blank form, the remainder of the supply for the year, four thousand, being the program of the Warren County (Kentucky) Society. The Warren county programs were used again this year, as the experience of the preceding years showed that the plans and purposes of the course of study were more readily understood by those not familiar with the work by using this program than through the outlines in blank form.

The outline for each weekly meeting has been printed in The Journal begining the first of September as was done last year. The value of this is apparent, for many of the requests state that the outline had been seen in The Journal.

Some of the societies that had tried the course the first or second year have given it up on account of the difficulty in getting the members to attend regularly, but on the other hand a very much larger number have taken up the work this year, showing for the year a marked increase in the number of societies. In most societies they also report that a much larger percentage of the members attend regularly the weekly and monthly meetings, indicating that the number of members has increased materially during the year.

The large number of states included in the list of societies shows that the interest in the course is rather widespread, but we are still convinced by the large number of requests coming in from the states and counties visited by Dr. McCormack that the man who knows the work from practical experience is best able to show to others the value of the course of study and arouse in them an interest in it.

One of the general topics for discussion this year is "Pharmacology and Therapeutics." In the program for this month one of the weekly meetings is devoted to a study of the organization, objects and rules of the Council on Pharmacy and Chemistry of the American Medical Association. In the Warren county program we also planned a meeting with the local pharmaceutical society, discussing the Admissions and Rejections to the U. S. P. We have also distributed with the outline the report of the Committee on Revision of the U. S. P., requesting each society to discuss these topics with the druggists. Reference is also made to the publications of The Journal press on these kindred subjects.

We see that in many of the state and private medical journals during the year, and in the meetings of the county secretaries of some of the state societies, the value of a systematic course of study has been discussed. These facts, in addition to the large number of letters received from the secretaries and members of the societies following the course, show the wonderful increase in the interest and enthusiasm in the course of study and its practical application to the needs of a large number of societies both in the smaller towns and in the larger cities.

The outline for the fourth year will be printed and ready for distribution by the first of August, permitting all who desire to begin the work on the last year of the cycle by the first of September.

The very frank statements from a large number of county society officers as to the value of the course of study in bringing doctors together and causing them to adjust in a satisfactory way their little personal differences, in addition to the value in a professional way derived from the actual study and thought given the medical topics, show that this has been by far the most successful year of the course of study.

Very respectfully,
Jno. H. Blackburn, Director.

Report of the Council on the Defense of Medical Research

During the past year the Council on the Defense of Medical Research has in the main been carrying out the program suggested by the work of its first year. This program has consisted in furthering the adoption of rules in medical laboratories, the publication of papers, and the distribution of information regarding the work of the Council and the data collected by it.

The regulations concerning the care of animals in laboratories have now been formally adopted by the faculties of 52 schools, including all of the large institutions, out of 77 schools that have reported the use of animals for experimental purposes. In several states all of the medical laboratories within their borders are now governed by these regulations. It is probable that soon they will be adopted everywhere in laboratories in which animal experimentation is carried on.

During the past year the following papers showing the relations between animal experimentation and practical medicine and surgery have been published in The Journal of the American Medical Association and reprinted as pamphlets for general distribution:

Vaccination and Its Relation to Animal Experimentation. Jay Frank Schamberg.
Animal Experimentation and Tuberculosis. E. L. Trudeau.
The Rôle of Animal Experimentation in the Diagnosis of Disease. M. J. Rosenau.
Animal Experimentation and Cancer. James Ewing.
The Ethics of Animal Experimentation. James Rowland Angell.
Animal Experimentation. The Protection it Affords to Animals Themselves and Its Value to the Live-Stock Industry of the Country. Veranus A. Moore.
The History, Prevalence and Prevention of Rabies and Its Relation to Animal Experimentation. Langdon Frothingham.
The Importance of Animal Experimentation in the Development of Our Knowledge of Dysentery, Cholera and Typhoid Fever. Mark Wyman Richardson.
Animal Experimentation in Relation to Our Knowledge of Secretions, Especially Internal Secretions. S. J. Meltzer.
Animal Experimentation in Relation to Protozoan Tropical Diseases. Harry T. Marshall.
Modern Antiseptic Surgery and the Rôle of Experiment in Its Discovery and Development. W. W. Keen.

Two other papers of general interest, one by Dr. Charles W. Eliot, entitled, "The Fruits of Medical Research with the Aid of Anesthesia and Asepticism," and another by Dr. W. W. Keen, entitled, "What Vivisection Has Done for Humanity," have been reprinted in pamphlet form for general distribution.

The collection of papers given above does not complete the series which the Council has arranged to have published. When the series is finished it will form a unique collection of data which have never been so thoroughly gathered together before. In most instances the statements are the testimony not only of experts in their several fields, but of the original observers to whose work constant reference is made. The scholarly character of the papers assures them, therefore, permanent value. The data thus collected should be serviceable for many years wherever agitation against animal experimentation may arise.

The work of the Council and the information collected in these papers have been given publicity in the daily press. The education of interested people is doubtless the next stage in the effort of the Council to develop an intelligent attitude toward animal experimentation. In this connection the formation of a society of laymen for the promotion of medical research has been discussed; during the coming year such a society will probably be further considered and possibly brought into organization.

Agitation is now most active in the State of New York. The Council has aided in meeting this agitation both by applying methods of publicity and by cooperation of the members of the Council with the New York medical organization. Since a larger number of legislatures meet next year than have met this year the chances are in favor of more attempts at hostile legislation than have this year appeared. The plans of the Council to control animal experimentation within professional lines will do much, it is believed, to offset the demands of the agitators for legislation which provides for meddlesome interference by uninstructed laymen.

W. B. Cannon, Chairman.

Report of the Committee on Patents and Trade-Marks

To the Members of the House of Delegates of the American Medical Association:

Your Committee, created at the Chicago meeting in 1908 to study the question of process and product patents on materia medica products and the advisability of securing the enactment of a bill to prohibit the patenting of materia medica products and also to prevent the registration of names of medicines as trademarks, reported last year at Atlantic City its conclusions—that the abolition of product patents on materia medica products was impracticable for reasons given in the report. It was recommended, however, that a committee be continued to keep track of legislation on the subject of patents, and if necessary, cooperate with bodies like the American Bar Association who are interested in the improvement of patent laws, and to attempt to secure court decisions against the improper use of names of medicines as trademarks by manufacturers if such action should seem advisable to the Committee and to the Trustees of the Association. In accordance with this recommendation, the original committee was continued.

During the year, your Committee has kept itself informed of measures proposed and introduced in Congress to change the present patent laws, but nothing has developed that has called for action by your Committee. No doubt changes will be proposed in the future, and all legislation on this subject should be carefully watched. This matter, however, is properly the function of the Committee on Legislation and we recommend that this subject in the future be referred to this Committee.

In our report last year, we referred to some of the questions relating to trademarks that are still in a state of confusion in the court decisions. As bearing on the right of manufacturers and owners to retain the use of names of products that have ceased to be brands, one decision of great importance has been rendered by the Supreme Court during the year in the case of Saxlehner versus Wagner, denying the claims of the petitioner to the exclusive use of the name "Hunyadi." The respondents manufacture a bitter water in Cincinnati and label it "W. S. Wagner's Sons Carbonated Artificial Hunyadi, Conforming to Fresenius' Analysis of Hunyadi Janos Springs." The petitioners sought an injunction against the use of "Hunyadi." The Court says that "there was no unfair competition and no fraud. The plaintiff had no patent for the water and the defendants have a right to reproduce it as nearly as they can. They have the right to tell the public what they are doing and to get whatever share they can in the popularity of the water by advertising that they are trying to make the article and think that they succeed. If they do not convey, but on the contrary, exclude the notion that they are selling the plaintiff's goods, it is a strange proposition that when an article has a well-known name that they have not a right to explain by that name what they imitate. By doing so, they are not trying to get the good will of the name but the good will of the goods. Although the application is different, the principle seems to be similar to the rule that when a patent has expired, descriptive words or even an arbitrary or personal name by which it has become known may be used if sufficient precautions are taken to protect the public from being deceived."

It would follow that a mixture whose composition is secret or a product on which the patent has expired could be imitated and described by the use of a name that has become identified with it, provided that the public is not deceived as to origin of the article.

While this decision does not fully cover the important question referred to last year as to the right of the manufacturer to trademark a catchy name which he then tries to identify with his product so that it may become in reality specific, it does show the tendency to the court to prevent any such evasion of the general principles of trademark rulings.

Your committee remains convinced of the correctness of the conclusions presented last year that the evils of trademarked names are to be remedied by the courts rather than by the enactment of new laws. However, it did not seem advisable to the Trustees of the Association that we should take the initiative in a suit for the purpose of getting a decision on these questions and no cases have arisen that have required our cooperation. This work must be done in the future and can properly be left to the Committee on Legislation, or to the Council on Legislation, etc., which has been proposed as a substitute for the present Committee. We therefore recommend that this subject also be so transferred and that the Committee be discharged.

Respectfully submitted,
C. S. Bacon, Chairman,
O. T. Osborne,
A. B. Cooke,
P. M. Jones,
H. C. Wood, Jr.

Report of the Committee on the Davis Memorial Fund

To the Members of the House of Delegates of the American Medical Association:

This is the first time the chairman of your committee ever appeared before a representative body of his profession with a sad heart. Each of the years since the appointment of this committee he has sought to actively interest its members in a project which seemed to him simple, comparatively insignificant and easy of execution. His plan of operation advised was to ask the profession of each state to obtain from its State Society or Association the appropriation of half the sum which seemed sufficient, dependent on the state member of this committee to raise an equal amount by private solicitation. This plan worked so well in his own state that he was encouraged to urge its adoption, especially since in this way every member of the profession in the United States could be considered as sharing in a voluntary offering of remembrance to the great founder of the American Medical Association. For reasons which need not be referred to here, Massachusetts had little sympathy and gave little support to our Association for much the larger part of its existence, yet my plan worked so well that it was easy to secure nearly double the amount of money which was thought to have been her share. For years New York was torn asunder by contentions which made the great body of the profession of the state indifferent to or in opposition to the Association. Yet through the kindly offices of Dr. Bryant and Dr. Wyeth a few members of the profession in New York City gladly contributed five hundred dollars. An equal sum will probably be appropriated by the state organization. Your committee had every right to expect the State of Illinois, and especially the great city of Chicago, the home of the Association and the almost life-long center of Dr. Davis' public activities, would furnish much more than its quota in commemoration of, in many respects, its first citizen. Great as Dr. Davis was as a medical practitioner, teacher and leader in his profession, many have felt that his public services to his city and state warranted the independent action of its citizens in commemorating him in imperishable bronze looking out on the lake, the waters of which, largely through his foresight and energy, have been given in ample and permanent supply to the thirsty city. It was supposed easy to raise $15,000 in Chicago alone for this purpose. Your treasurer will tell you that beside his own generous gift, that of Dr. Quine, and the Davis Memorial Service Fund, almost nothing has been done where most was expected.

The first year that your committee was appointed was marked by the unprecedented disaster to the great city of San Francisco, and it was felt that every effort should be made by our profession to relieve its suffering. Although very many wealthy members of our profession in San Francisco were utterly ruined financially, they, for the most part, heroically refused assistance, and the $5,000 voted by our Association for this purpose was refused with thanks. The last contribution received for the Davis memorial was from Dr. R. F. Rooney, member of our committee from California, in the sum of $130, regretting that this amount was so little, owing to the great calamity which had befallen them. Dr. Anders, member of our committee from Pennsylvania, makes report of progress with a contribution of about $400. Dr. Jepson of Iowa reports that his state society this year proposes to contribute $300. At the last meeting of the Association it was voted to furnish $5,000 of a total of $25,000.

At the beginning of this year I asked for a renewed effort of our committee to finish the work so long delayed. I reinforced the appeal by writing to each one of the presidents of the state societies and associations for a cooperative effort, with the request that all the funds so raised should be sent directly to our treasurer and not to me. I have asked Dr. Billings for a statement to be incorporated in this report, which is appended.

I must confess to a great disappointment. No man could present a more worthy object, not so much for the solicitation of funds as the request for the privilege extended to a great profession of making a public recognition of its really great and worthy founder. This no one questions. Again, no one holds more highly than myself the honor and generous attributes of the medical profession, which largely under the leadership of Dr. Davis' co-association work has placed America in the acknowledged front rank of medical attainment in the world. The medical journal of this Association, largely established by Dr. Davis' untiring effort, who without compensation for years was its first editor, is the acknowledged leader in national and international medical journalism.

A brief analysis of our treasurer's report shows that only six states have made contribution to the fund. This House of Delegates, representatives of all the states, subscribers to the *Journal*, numbering over fifty thousand, the great army of our profession which is in excess of one hundred thousand in the United States—all know that this neglect is little less than a disgrace.

The inevitable conclusion to which the chairman of your committee has arrived is that, notwithstanding his persistent and continued efforts, he is unfitted for the position to which you elected him and in which he has gladly served. He recognizes that it would have been far more fitting to have had the initiating of the movement arise in the great city which Dr. Davis so well represented. He regretfully tenders to you his resignation with the request that some leading member of the profession in Chicago may be carefully selected to complete the work which in his hands has been, if not a failure, a bitter disappointment.

REPORT OF THE TREASURER OF THE N. S. DAVIS MEMORIAL FUND

Frank Billings, Treasurer

Aug. 1, 1906—Amount deposited in the Northern Trust Company Savings Department		$ 192.50

Total		$2,771.35

The following letter is herewith transmitted to the House of Delegates:

Dr. Henry O. Marcy, May 1[illegible] 1910.

Chairman of the Davis Memorial Fund, Boston, Mass.

Dear Sir:—I herewith present you, as chairman of the Davis Memorial Fund, my resignation as treasurer. I desire my resignation to take effect at the time of the meeting of the American Medical Association at St. Louis in June. I shall be ready to transfer the fund of the memorial to my successor as soon as he shall have been elected.

Very truly yours,

Frank Billings.

Respectfully submitted.

Henry O. Marcy,
Chairman.

May 10, 1910.

Report of the Committee on Insignia

To the Members of the House of Delegates of the American Medical Association:

Your special committee which was instructed at the Atlantic City meeting in June, 1909, to devise a suitable insignia for the Association to take the place of the present one, begs leave to submit the following report:

1. It is perfectly apparent that it is desirable, if not necessary, to change the present insignia which contains a Red Cross. In 1906, representatives from the different civilized governments of the world met at Geneva for the purpose of amending the original article of the Geneva Convention for the amelioration of the condition of the wounded in the armies in the field. The United States was represented at this convention and is one of the signatory powers.

Article 27 of this Convention provides that "the signatory powers whose legislation may not now be adequate engage to take or recommend to their legislatures such measures as may be necessary to prevent the use, by private persons or by societies other than those upon which this convention confers the right thereto, of the emblem or name of the Red Cross or Geneva Cross, particularly for commercial purposes by means of trademarks or commercial labels."

There is no law in the United States under which an organization which was using the Red Cross as an insignia can be compelled to discard it, but it is believed that this powerful organization should be one of the first to assist the government in carrying out its obligations. It is also believed that any action this Association may take in discarding the Red Cross in conformity to the 1906 Geneva Convention will be a powerful factor in encouraging other organizations to do likewise. During the present session of congress a bill was introduced, and will probably become a law, attaching a penalty to any unauthorized organization using the Red Cross. While a paragraph may be inserted in this bill exempting organizations from its penalty which used this insignia prior to 1906, it is hardly believed the American Medical Association desires to avail itself of this section.

2. In getting up a new insignia your committee believes that it should convey a definite meaning both in colors and design. It was easy to determine that Scarlet and Gold have been the medical colors since ancient times. and your committee is in harmony that these colors should be the basic ones of the insignia.

3. It was also determined by your committee that the true ancestral symbol of the healing art is the Knotty Rod and serpent of Æsculapius.

4. There has been some disagreement by the members of your committee in assembling the Knotty Rod and serpent and Scarlet and Gold colors into a suitable insignia. One member of the committee, Dr. Cantrell, believes that the Eagle should play an important part in this insignia, while the other four members of the committee, Drs. Gerhard, Wolfe, Taneyhill and Ireland, believe that the insignia should be constructed without the Eagle.

Samples of both designs have been distributed and the question of deciding which shall be adopted is left to the members of the House of Delegates with the recommendation of the majority of the committee that the insignia without the Eagle be accepted.

M. W. Ireland,
G. Lane Taneyhill,
Samuel Wolfe,
Samuel P. Gerhard,
C. E. Cantrell.

Report of the Committee on Relief Fund and Tuberculosis Sanatorium for Physicians

To the Members of the House of Delegates of the American Medical Association:

The profession of medicine exists to assist those who need the help of others; and to conserve whatever of comfort and usefulness is possible for impaired lives. Now that those engaged in each craft or profession generally acknowledge the tie of a common occupation as binding them to organizations for the assistance of their less fortunate comrades, it is appropriate that the American Medical Association should carefully consider what can be done for the unfortunate and disabled members of the medical profession.

At a time when the whole people is being aroused to a campaign against tuberculosis, it is also proper that the American Medical Association consider with care what may be done to help the recovery of physicians stricken with this disease; to remove even a suspicion of danger that the diseased physician may be a carrier of the disease, and to establish a center for *investigation* and education with regard to tuberculosis that may make the whole profession more efficient in its warfare against this plague. Your Committee therefore asks the careful attention of the House of Delegates, and of the Association at large, to the questions it has been considering.

To secure such data as were available to throw light on the existing situation with regard to the relief of indigent and disabled members of the profession, and those dependent on them, and to collect data regarding the prevalence of tuberculosis in the profession, the following circular letter was sent to each state medical society, and to the medical journals published by such societies:

To the Secretary of Each State and County Medical Society, and Other Interested Members: At the last meeting of the American Medical Association at Atlantic City the following report of the Committee on Miscellaneous Business was adopted:

"The committee recommends that the President of this Association appoint a committee of five members to inquire into the desirability and practicability of establishing under the auspices of the American Medical Association a fund for the assistance of physicians disabled by sickness, and for a sanatorium for the treatment of such members of the Association as may be afflicted with tuberculosis or similar diseases; such committee to report to the House of Delegates at the next annual meeting of the Association."

As basis for wise action the committee urges that the officers of state and county medical societies, and others interested in the subject, should at the earliest possible date forward to the secretary of the [illegible] Dr. A. C. Magruder, Colorado Springs, Colo., answers [illegible] es, with some account of any special cases th[illegible] the special need for provision for disabled members of our profession:

1. Is there any provision by your state medical society, or local society, for the care of destitute and disabled physicians and those dependent on them? If so, how is such care provided?

2. What number of instances of special need for such assistance (or sanatorium treatment), have arisen in your locality within the last five years, and what number of your members need such assistance now?

3. About how many members of your county medical society are at present afflicted with tuberculosis or similar diseases; or have, within the last five years, died or withdrawn from professional work on account of such disease?

It is earnestly requested that this matter be brought before each county and state society at its next regular meeting, and that the desired information be furnished our committee at the earliest possible date.

Compared with the number of state and county medical societies the number of replies has been meager, but they represent 17 states scattered in all parts of the country from Massachusetts to Nevada, and from North Dakota to Texas. They include such information as is obtainable from the local organizations in our largest cities, as well as reports from some of the small county societies of country districts. While, with longer time at our disposal, a larger correspondence might have secured a greater mass of material, it is not likely that this would have given a different, or much more definite, impression with reference to existing conditions than is now available. As has been pointed out by some of our correspondents, there exist no records on which complete returns could be based.

From the data now at our disposal it appears: Except in three of our largest cities there are no organizations anywhere in this country to care for destitute and disabled physicians and those dependent on them; or which have at their disposal permanent funds devoted to that purpose.

In the cities alluded to the organizations, which have been in existence for periods of thirty to fifty years, have accumulated considerable funds, the interest of which is fully employed in affording the relief for which the associations were organized. One of these has invested funds amounting to $30,000, and has given assistance to fourteen beneficiaries and two annuitants. In one case the assistance given the widow of a physician amounted to $200 per year for fifteen years.

The replies from several isolated localities show that cases of need, so urgent as to appeal strongly to the sympathies of colleagues of the local profession, occur in every part of the country. The average is about four reported instances to each ten county societies.

The responses to the third question of the committee show, after excluding parts of the country sought for the climatic treatment of tuberculosis, that in ten county societies seven instances of tuberculosis are reported as now existing, or known to have occurred in the recent past, among the members. But it should be noted that none of the larger county medical societies attempts to answer this question. The statement is made that no data exist on which an intelligent answer could be based.

As bearing upon the frequency of tuberculosis among physicians, the secretary of your committee recently attempted to ascertain the number of physicians who had come to Colorado on account of tuberculosis. Of 504 who replied to his inquiries 86, or over 17 per cent., had removed to that state on account of tuberculosis affecting themselves. Inquiry of three of the larger sanatoriums in Colorado, which are under strictly medical control, showed that among 2,391 male patients treated for tuberculosis, 31 were physicians, or one in every 77.

If we take the conservative estimate of one in every 350 physicians incapacitated for their work by tuberculosis, it would appear that there are constantly 100 of our members who need the help of a sanatorium. They would have an increased chance for recovery, an improved expectation of life by sanatorium treatment under the best climatic conditions. And in the total medical profession of the country there would be about 300.

The prolonged course of tuberculosis, the delusive hope cherished by consumptives of a speedy restoration, the tendency to premature confidence, taking beginning improvement for practically complete cure, the demoralizing influence of self-treatment on most physicians affected with this disease, make it extremely important that the physician stricken with tuberculosis should have the opportunity and the discipline of a sanatorium, supported and administered by the medical profession. And this need is quite irrespective of the ability of the patient to pay for his care and maintenance.

In the great cities or among the scattered population of remote country districts, wherever men suffer from the accidents of mines or machinery, or women face the ordeal of childbirth; wherever accident, epidemic influence, or the unfavorable conditions of daily life entail mutilation, suffering, illness and death, are members of our profession, giving their first thought and their best effort to the assistance of the sick, rather than to provision for the emergencies which may overtake themselves.

If altruism, the broader application of a spirit of brotherhood, have any worthy place in the life of a civilized people, it is in providing for those stricken by accident or disease in the performance of their duty; who have been too much engrossed in taking care of others to provide for themselves. We encounter no finer characters than are sometimes found among physicians of good ability, complete training, and great industry, who have given their best efforts to help those who could do little or nothing in return, and persisted in them until the helper could no longer help. The medical profession can ill afford to neglect those whose character gives it the highest standing in the eyes of the world. The public can ill afford to ignore the claims of those who wear themselves out, or die, in its service—who do what is to be done without first stopping to demand security for compensation. To pension the soldier, the fireman, the teacher, the faithful servant of the corporation, and neglect the physician would show a low sense of the relative value of faithful services rendered.

We are convinced that if a responsible, widely-known, representative organization will undertake the care and administration of funds collected for this purpose, little difficulty will be found in obtaining from the more fortunate members of the profession, and from grateful patients and liberal laymen, all the money necessary for the relief of the comparatively few medical men rendered unable to meet the more severe emergencies of life. It is clear that the instances in which the physician must depend on financial assistance from others are so exceptional that in large parts of our country permanent funds for meeting these emergencies cannot be established and kept up, either by the local profession or the county or state medical societies.

What is needed is a central fund by which the needy physician in any locality can be afforded relief. The relief can be given through a local relief organization, or a county medical society, and safeguarded by requiring that a certain percentage of the amount expended shall be raised by the local medical organization. But many localities, many state societies, cannot establish relief funds; and no state society can guarantee the permanence and proper administration of such a fund so well as can the American Medical Association. The sanatorium care of the tuberculous is also impracticable for isolated local or state medical societies. It can best be carried out under the most favorable climatic conditions, where the extent of country served will give a comparatively constant number of patients.

We therefore recommend: That the House of Delegates authorize the appointment of a committee with adequate appropriation for the performance of its duty, to draw up and report to the House, a plan for the organization of a corporate body to receive and administer funds for the relief of physicians disabled by disease, or accident, or those dependent on them; and to establish a sanatorium for the treatment of physicians suffering from tuberculosis; such plan to conform in a general way to the following:

A. A majority of its governing body (trustees) to be chosen by the American Medical Association, a portion each year for overlapping terms. A minority of the governing body may be chosen by contributors to the funds.

B. The income should be derived from funds entrusted to the corporation for that purpose, rather than by a fixed tax on the members of the American Medical Association.

C. The funds to be expended with the cooperation of local organizations, under sufficient guarantee and on proper vouchers.

D. A sanatorium to be established for the treatment of physicians afflicted with tuberculosis where those able to pay for such treatment will be expected to do so; but where those unable to pay for it shall receive the same assistance.

E. Such sanatorium to be situated where favorable climatic conditions prevail, and equipped for the thorough scientific study and treatment of tuberculosis and allied diseases.

Edward Jackson, Chairman,
Jefferson R. Kean,
A. T. Bristow,
H. B. Ellis,
A. C. Magruder, Secretary.

Report of the Committee on Uniform Regulation of Membership

To the Members of the House of Delegates of the American Medical Association:

This committee was created at the Chicago meeting in accordance with a recommendation made by the General Secretary. At the Atlantic City Session in 1909, the committee presented a lenthy report consisting mainly of tabulated data regarding the regulation of membership in the various state associations. The committee recommended that all of the state associations be requested to make their fiscal year conform to the calendar year and to request their component county societies to adopt the same rule, that the committee be continued, that it be increased by the addition of four state secretaries and that it be instructed to continue its work of securing uniform regulation of membership by county and state societies.

The House of Delegates in addition to the work originally assigned to this committee, also referred to it the resolution of Dr. W. H. Sanders of Alabama, regarding the revision of the constitution and by-laws and instructed the committee to report to the House of Delegates in 1910 such amendments as it might deem advisable. In addition, the question of uniform regulations for the disciplining of members was also referred to the committee. We therefore beg to submit the following report, which is presented in three sections:

(1.) Recommendations for amendments to the constitution and by-laws.

(2.) Recommendations for amendments to the model constitution and by-laws for county and state societies regarding the disciplining of members.

(3.) Additional material, discussion and recommendations regarding the uniform regulation of membership.

I

RECOMMENDATIONS FOR CHANGES IN THE CONSTITUTION AND BY-LAWS OF THE AMERICAN MEDICAL ASSOCIATION

CONSTITUTION

Article 4.—Constituent Associations

Amend present article to read as follows:

State and territorial medical associations which have or which hereafter may become organized in accordance with the general plan of organization of the American Medical Association, and which have declared by resolution their allegiance to the said American Medical Association, and which shall agree with other state and territorial medical associations to the formation and perpetuation of the House of Delegates of the American Medical Association, shall be recognized as constituent associations on presentation of evidence that they have complied with the above conditions and on acceptance of their application for recognition by the House of Delegates.

Article 5.—House of Delegates

Second sentence to be amended to read as follows:

It shall consist of delegates elected by the constituent associations and by the Scientific Sections of the American Medical Association, and appointed from the medical departments of the Army, Navy, and from the United States Public Health and Marine-Hospital Service, etc.

Article 12.—Amendments

Amend to read:

The House of Delegates may amend any article of this constitution at any annual session, provided that the proposed amendment shall not be acted on until the annual session next following that at which it was introduced and providing that three-fourths of the voting members of the House of Delegates registered at the session at which action is taken vote in favor of such change or amendment.

BY-LAWS

Amend chapters 1, 2 and 3 to read as follows:

Chapter 1.—Membership

Section 1.—Classes of members.—There shall be four classes of members: Regular members, associate members, ex-officio members, and honorary members.

Sec. 2.—Regular members.—Any physician reported as a member in good standing of the state association and of the constituent association of the state in which he resides by the secretary, who shall make application on the prescribed form and who shall pay the annual dues and the subscription to The Journal of the American Medical Association for the current year shall be entered as a member.

Sec. 3.—Tenure of Membership.—Regular membership in this Asssociation shall continue only so long as the individual is a member in good standing of the constituent association of the state in which he resides. When the general secretary shall be officially informed by the secretary of the constituent association of the state in which a member resides that he is not in good standing the general secretary shall remove his name from the membership roll of the American Medical Association and shall notify him of the action taken, together with the reason therefor. It shall be the duty of every member of this Association to maintain his good standing as a member of the constituent association of the state in which he resides in accordance with the by-laws thereof.

Sec. 4.—Removal of Members.—A member removing from one state to another shall become a member of the constituent association of the state to which he removes within one year after his removal. He shall retain his membership in the constituent association of the state from which he removes until he has acquired membership in the constituent association of the state to which he removes. Failing to comply with either of these requirements, he shall be dropped from the roll of members of this Asssociation.

Sec. 5.—Delinquency.—Any member who fails to pay his annual dues and the subscription to The Journal for one year shall be dropped from the roll of members, provided due notice from the general secretary shall be previously mailed to the last known address of the member.

Sec. 6.—Reinstatement.—Any member dropped for either non-membership in his state association or for non-payment of dues shall, if he desires reinstatement, comply with the provisions of Section 1 of this Chapter, the same as a new applicant, except that members dropped for non-payment of dues, and who apply for reinstatement within one year, may be reinstated by paying all indebtedness, including dues and the subscription to The Journal for the current year.

Sec. 7.—Associate Members.—The following shall be eligible to associate membership: Teachers of sciences allied to medicine; physicians engaged in teaching or laboratory work, not eligible to regular membership; dentists holding the degree of D.D.S. who are members of state or local dental societies; pharmacists who are active members of the American Pharmaceutical Association. Associate membership shall be limited to residents of the United States.

Sec. 8.—Election of Associate Members.—Applications for associate membership shall be endorsed by the officers of a section and approved by the same section. The application shall then be sent to the general secretary for confirmation by the House of Delegates. Applications from dentists shall be referred to the Section on Stomatology; applications from pharmacists shall be referred to the Section on Pharmacology and Therapeutics. Associate members shall have the same privileges and be subject to the same conditions as regular members. The general secretary shall, between annual sessions, accept applications for associate membership endorsed by the chairman and secretary of the section through which application is made such acceptance to be subject to confirmation by the House of Delegates at the annual session following.

Sec. 9.—Ex-Officio Members.—Commissioned medical officers of the United States Army, United States Navy and the United States Public Health and Marine-Hospital Service shall be ex-officio members of this Association so long as they retain their connection with their respective services. Resignation or dismissal from the service shall be equivalent to resignation of membership in this Association. Ex-officio members shall not be required to pay dues and shall not receive THE JOURNAL of the American Medical Association except by personal subscription.

Sec. 10.—Honorary Members.—Physicians of foreign countries may be elected as honorary members by the House of Delegates on nomination of a section. Nominations from sections shall be submitted to the House of Delegates on the afternoon of the second day of the annual session. Not more than three honorary members shall be elected in any one year.

Sec. 11.—Invited Guests.—Teachers, students of sciences allied to medicine and distinguished physicians of foreign countries may be invited by the general officers or by the officers of a section to attend an annual session and to take part in the scientific work. They shall be designated as invited guests and shall hold their connection with this Association until the close of the annual session to which they are invited. They shall be entitled to participate in the scientific and social functions of the Association.

Sec. 12.—Members from Foreign Countries.—The House of Delegates may provide for membership under proper restriction from the members of recognized medical societies of foreign countries.

Chapter II.—Registration

Section 1.—No member shall take part in the proceedings of the Association or of any of the sections until he has registered his name and address in the registration office and has paid all dues and subscriptions for the current year.

Sec. 2.—Section Affiliation.—A member on registering shall designate the section in which he wishes to be enrolled, but no member shall register in more than one section at any annual session.

Chapter IV.—Qualifications. Term, Apportionment and Registration of Delegates

Section 2 to read as follows:

Delegates Elected for Two Years.—Delegates from constituent associations shall be elected for two years. Constituent associations entitled to more than one representative shall elect their representatives so that one-half, as near as may be, shall be elected each year. Delegates elected by the sections or appointed from the United States Army, Navy and United States Public Health and Marine-Hospital Service shall hold office for one year.

Sec. 3.—Apportionment of Delegates.—At the annual session of 1903, and every third year thereafter, the House of Delegates shall appoint a committee of five on reapportionment, of which the president and the general secretary shall be members. This committee shall apportion the delegates among the constituent associations in accordance with Article 5, Section 2, of the Constitution, and in proportion to the membership of each constituent association on April 1 of the year in which the apportionment is made as shown by the certificates of membership submitted by the secretaries of the constituent state associations. This apportionment shall take effect at the annual session next succeeding that at which the apportionment is made and shall prevail until the next triennial apportionment whether the membership of the constituent associations shall increase or decrease.

Sec. 4.—Registration of Delegates.—Each delegate from a constituent association before being seated shall deposit with the Committee on Credentials a certificate signed by the president and secretary of his constituent association stating that he has been legally and regularly elected a delegate to the American Medical Association for a definitely stated term. Each delegate from a section shall present credentials signed by the chairman and the secretary of the section which he represents. The delegates from the government services shall present credentials from the surgeon-general of the department which he represents.

Sec. 5.—A Delegate Once Seated to Retain His Seat for the Entire Session.—The credentials of a delegate having been accepted by the credentials committee and his name placed on the roll of the house, he shall remain as the duly accredited delegate of the body which he represents until final adjournment of the session and his place shall not be taken by any other delegate or alternate.

Chapter V.—Procedure of House of Delegates

Sec. 2.—Limit of Time for Introduction of New Business.—No new business shall be introduced into the House of Delegates after the third day of the annual session, unless with unanimous consent; and such new business, whether in the form of a motion, a resolution, a memorial, or otherwise, shall require the unanimous vote for adoption.

Chapter VI.—Meetings of the House of Delegates

Sec. 2.—Special Sessions.—Special sessions of the House of Delegates shall be called by the president on a written request of 27 members of the last House of Delegates, provided that they represent the majority of the constituent associations. When a special session is called by the president the general secretary shall mail a written or printed notice to the last known address of each member of the last House of Delegates at least twenty days before such special session is to be held, in which notice shall be specified the time and place of meeting, and, in general terms, the object of such special session. No other business shall be transacted at the special session than that specified in the call.

Chapter VII.—Nomination, Election and Installation of Officers, Trustees, Associate and Honorary Members

Section 1.—Nominations.—Nominations for office shall be made orally, but no nominating speech shall exceed two minutes in length. The treasurer shall be nominated by the board of trustees.

Sec. 2.—Method of Holding Elections.—All elections shall be by ballot and a majority of the votes cast shall be necessary to elect. In case no nominee receives a majority of the votes on the first ballot the nominee receiving the lowest number of the votes shall be dropped and a new ballot taken. This procedure shall be continued until one of the nominees receives a majority of all the votes cast, when he shall be declared elected.

Sec. 4.—Associate and Honorary Members.—Nominations for associate and honorary membership from the sections shall be referred without debate to the Committee on Sections and Section Work, which shall report its recommendations to the House of Delegates. The election of associate and honorary members shall immediately follow the election of officers.

Sec. 5.—Installation.—The general officers of the Association, except the president, shall assume their duties at the close of the last meeting of the annual session at which they are elected.

Chapter VIII.—Duties of Officers

Section 1.—President.—The president shall preside at the general meeting and at the meetings of the House of Delegates, and shall perform such duties as custom and parliamentary usage require. On the morning of the first day of the annual session following his election he shall deliver an address at the general meeting not exceeding forty minutes in length on such matters as he may deem of importance to the Association. He may at any time make suggestions in writing to the House of Delegates or to any special or standing committee.

Sec. 3.—General Secretary.—The general secretary shall give due notice of the time and place of all annual and special sessions of the Association and of the House of Delegates in THE JOURNAL of the American Medical Association. He shall send an official notice of each annual or special session to the secretary of each constituent association and to the secretary of each section. He shall keep the minutes of the House of Delegates. He shall notify members of committees of their appointment and of the duties assigned to them. He shall verify the credentials of the members of the House of Delegates and shall provide a registration book in which shall be recorded the name of each delegate in attendance at each session, together with that of the association, government service or section which he represents. He shall prepare a roll of the delegates attending each session to facilitate voting by roll-call. He shall prepare for publication the official program of each session, and shall perform such other duties as pertain to his office or as may be directed by the House of Delegates or the board of trustees. The general secretary's salary shall be fixed by the board of trustees.

Chapter IX.—Board of Trustees

Sec. 2.—Trustees to Control Sessions.—Last two sentences of the section to read as follows: It shall also have control of all exhibits. The board of trustees, in its discretion, may appoint a local committee of arrangements, which shall be at all times under the control of the board of trustees.

Chapter X.—Committees

Section 1.—Classification of Committees.—Amend by adding to the section the following: In case of vacancies in committees occurring during the interval between annual sessions the president shall have the power to appoint members to fill the vacancies until the next annual session.

Sec. 2.—Membership of Committees.—Reference committees shall be appointed by the president from among the members of the House of Delegates............etc.

Sec. 3.—Standing Committees.—Amend to read as follows: Standing committees shall be the following:

(a) Committee (or Council) on Medical Legislation.
(b) Council on Medical Education.
(c) Committee on Transportation and Place of Session.

Strike out section 4.—Judicial Council.

Sec. 5.—Committee on Medical Legislation to become Sec. 4 and to be replaced by new Section to be reported by the Committee on Reorganization of Standing Committees.

Sec. 7.—Council on Medical Education—to become Sec. 5.

Sec. 6.—Committee on Transportation and Place of Session to remain unchanged.

Present Section 8 to be stricken out.

Present Section 9—Reports of Standing Committees—to become Section 7 and to read as follows:

Sec. 7.—Reports of Standing Committees—Reports of Standing Comittees shall, so far as possible, be transmitted 30 days before the annual session to the General Secretary who shall have them printed for distribution to the members of the House of Delegates.

Present Section 10 to become Section 8.

Present Section 11 to become Section 9. Last sentence to be amended to read: These committees shall serve during the session at which they are appointed.

Page 24, paragraph 6, to read as follows: A Committee on Amendments to the Constitution and By-Laws to which shall be referred all proposed amendments to the constitution and by-laws.

Paragraph 9 to read as follows: A Committee on Miscellaneous Business to which shall be referred all business not otherwise provided for.

Sec. 10.—Appeals from Decisions of State Associations.—Questions involving the ethical conduct or the membership rights of individual members shall be considered by the House of Delegates only on an appeal from the decision of the constituent association and then only in case some portion of the constitution of this Association is involved; except that in case of a dispute between two or more constituent state associations, the House of Delegates of the American Medical Association shall have original jurisdiction. Appeals from members, or protests, or complaints from constituent associations shall be referred without debate to a special committee of five selected by the House of Delegates, no member of which shall be a delegate from the constituent state association interested in the case. The Committee shall consider the case, giving at least twenty-four hours' notice of the time and place of the hearing to all the parties involved. The Committee shall report its findings and recommendations to the House of Delegates which shall consider the report in Committee of the whole House. Vote on the adoption of the report of the Committee shall be by ballot and the decision of the House of Delegates shall be final.

Chapter XII.—Sections

Sec. 2, page 26.—Officers of Sections.—The third sentence to be amended to read as follows: Each Section shall also elect annually one delegate and one alternate to the House of Delegates of the American Medical Association to serve one year.

Sec. 3, page 27.—Election of Officers.—The first sentence to be amended to read as follows: The election of officers shall be the first order of business of the morning meeting of the Section on the third day of each annual session.

Sec. 5, page 28.—Executive Committee.—Second and third sentences to read as follows: In case of absence from a session of a member of the executive committee, the vacancy shall be filled by the chairman. The executive committee shall examine and pass on all papers.....................etc.

Sec. 6.—Meetings.—Strike out everything after the word "decide."

Sec. 7.—Who May Take Part in Section Work.—Section to read as follows: The right to present papers before a Section, to take part in its discussions and to participate in its business and scientific deliberations shall be limited to members.

Sec. 9, page 29.—Time at Which Titles Must Be In.—Titles of papers to be presented to the Section must be in the hands of the Secretary of the Section at least thirty-five days before the first day of the annual session. With the title, the writer shall submit an abstract of the paper not less than thirty or more than one hundred and fifty words in length and an estimate of the time required to read his paper.

Sec. 12.—Can Present Papers Before Only Two Sections.—Amend to read as follows: No member shall have the right to present a paper or papers before more than two Sections at any annual session. When more than one Section is to be addressed, the titles and abstracts of both papers must be submitted to the secretaries of both the Sections before which the papers are to be read.

Chapter XIII.—Publication.

Sec. 2.—Papers Must be Ready for Publication.—Page 30 to read as follows: Each author shall hand his paper to the secretary of the Section immediately after it is read. The secretary shall endorse thereon that it has been read and shall hand it to the chairman of the executive committee. All papers approved by the executive committee shall be returned to the secretary of the Section who shall at once forward them to the editor of The Journal.

Chapter XVI.—Amendments to the By-Laws

Page 32 to read as follows: These by-laws may be amended by a three-fourths vote of the House of Delegates, provided that no amendment shall be acted on until the day following that on which it is introduced, except that the Board of Trustees may, by unanimous vote, make such changes and such changes only in the By-laws as may be required to adapt them to the rules and regulations of the United States postal authorities.

II

RECOMMENDATIONS REGARDING AMENDMENTS TO THE CONSTITUTION AND BY-LAWS OF COUNTY, STATE, AND AMERICAN MEDICAL ASSOCIATIONS, COVERING THE DISCIPLINING OF MEMBERS

COUNTY SOCIETIES

Amendment to take the place of Section 7, Chapter 1, page 7, model constitution and by-laws for county societies:

Sec. 7.—A member who is guilty of a criminal offense or of gross misconduct either as a physician or as a citizen, or who violates any of the provisions of this constitution and by-laws, shall be liable to censure, suspension or expulsion. Charges of any of the above offenses or of unethical or unprofessional conduct may be preferred by any member against any other member. Such charges shall be made in writing and shall specify the exact nature of the offense charged, as well as the time, place and circumstances of the offense. Written charges and specifications shall be filed with the secretary of the county society to which the member accused belongs within two years of the date of the offense charged. Specifications and names of witnesses to be summoned shall be filed with the charges which shall be signed by the member making the charges.

On receipt of properly prepared charges against a member, the secretary shall immediately transmit them to the chairman of the Board of Censors and shall at the same time furnish a copy of the charges to the accused. The Board of Censors shall set a time for hearing the charges of which due notice shall be sent both to the accuser and to the accused but no hearing shall be held nor any action taken by the Board of Censors within ten days of the presentation of the charges to the accused. The accused may be represented by any other member of the society but not by a non-member. He shall be allowed to introduce witnesses and documentary evidence and to cross-examine the witnesses of his accuser. The accused shall also be allowed to testify in his own behalf if he so desires. The Board of Censors shall have the right to examine the witnesses presented by either side but shall not have the right to summon witnesses.

The attendance at the hearing of the case shall be limited to the Boards of Censors, the two principals, and their representatives and witnesses. If the accused so desires, however, the hearing shall be public.

The Board of Censors within five days after the termination of the hearing shall prepare a report stating (1) that the charges are not sustained, or (2) that the charges are sustained and that the accused be (a) censured, (b) suspended for a definite period, or (c) expelled. Censure or suspension shall require a two-thirds vote of the members present and voting. Expulsion shall require a three-fourths vote of those present and voting. The report of the Board of Censors shall not be considered except at a regular meeting or at a special meeting called for this purpose and in either case, due notice that the report will be presented and voted on at the meeting shall be sent by the secretary to each member of the society. No action shall be taken by the society in any case until at least six weeks have elapsed since the filing of the charges.

A member found guilty of charges preferred against him may appeal to the Council of the state society provided his appeal is filed with the secretary of the Council within three months after the meeting of the county society at which his case was decided. Such an appeal shall only be made on the grounds of the method of procedure of the Board of Censors of the county society in deciding the case and shall not involve the hearing of the original case. In appealing to the Council of the state society, the member making the appeal shall specify exactly what are his grounds of complaint and shall present extracts from the proceedings of the Board of Censors of the county society as a part of his appeal.

STATE ASSOCIATIONS

Amendment to the model constitution and by-laws of state associations to take the place of Section 3, Chapter VII, page 18.

Sec. 3.—The Council shall be the Board of Censors of the state association. It shall hear and decide all questions involving the right and standing of members and all questions of an ethical nature on which an appeal is taken from the decision of the component county society. Appeals must be filed in writing with the secretary of the Council within three months after the meeting of the county society at which the case was decided. Appeals shall be limited to questions involving the manner in which the trial was conducted by the Board of Censors of the county society or by the county society itself. The appeal shall state specifically the grounds on which the appeal is taken and shall be accompanied by properly certified extracts from the proceedings of the Board of Censors or of the county society. The Council of the state association shall consider the appeal at the first regular meeting held after the appeal is filed. A member appealing from the decision of his county society may present his case in person or may be represented by any other member of the state association. The Council shall have the authority to call for the original records of the case and after proper hearing may (1) affirm the finding of the county society; (2) return the case to the county society for a rehearing; (3) reverse the decision of the county society. The decision of the Judicial Council of the state association shall be final on all questions relating to individual conduct or the rights of individual members.

In cases involving the constitution of the American Medical Association, the member concerned may appeal from the decision of the Judicial Council of the state association to the House of Delegates of the American Medical Association.

AMERICAN MEDICAL ASSOCIATION

(See recommendations for changes in the constitution and by-laws of the American Medical Association, Part 1 of this report, Chapter X, Section 10.)

III

RECOMMENDATIONS REGARDING THE UNIFORM REGULATION OF MEMBERSHIP

1. In its report for 1909, the Committee recommended that all state associations be requested to make their fiscal year conform to the calendar year and that component county societies be requested to adopt the same rule. The adoption of this recommendation by all component county and constituent state organizations will give us a uniform fiscal year coinciding with the calendar year, and running from January 1 to December 31. This recommendation is renewed and its importance urged on state associations.

2. It is further recommended that rules be adopted by all county and state organizations providing that membership shall be good only for the year for which dues are paid; that is, that the roll for each county and state association be made up each year to include as members in good standing only those who have paid their dues on or before a certain date. This is necessary in order to prevent the confusion caused by the rules existing in many societies, whereby a physician once a member is regarded as a member until he is formally dropped. In some states, a member cannot be dropped until he is at least three years in arrears. This causes much confusion as a member who has not paid his dues for the current year is not in good standing and yet is still a member. Under such conditions, we ave three classes: 1. Members in good standing. 2. Members not in good standing, but under suspension. 3. Non-membe It is the second class which causes the trouble, as they have ot the rights of members, yet are still members. As the rules garding suspension and the length of the period of suspension ffer in the various state associations, it is necessary in order pass on such cases, to keep the local variations constantly in m l in order to be able to know the exact standing of each mem r. If the entire system of suspension were abolished, we wou then have only two classes: Members and non-members, and physician would only be a member of his society in case he paid his dues before a certain date. As soon as members b me accustomed to this plan, it will be found that the collec of dues and the sending in of reports from county societies l be greatly simplified and facilitated.

As far as the exact period is concerned, various dates have been suggested. For county societies, it has been suggested that reports be made on February 1, March 1, or April 1, allowing the county secretary one, two, or three months in which to collect the dues from the members. Probably, in the beginning, it would be advisable to be as liberal as possible and to allow county secretaries three months in which to collect dues from members, calling for reports from each county society for the year on March 1. The state secretary could then make up the roll of the state society for the current year by combining the reports received from all the county societies. In this way, the state secretary's roll would be made up anew each year, the old one being entirely discarded. A complete roster could then be prepared and a copy sent to the General Secretary on April 1, thus permitting the entire membership records of the Association to be revised by May 1 so that the exact status of each member would be known before the annual meeting of the Association.

3. Members Joining During the Year.—Any one becoming a member of a county society during the year could be reported to the state secretary on a uniform report blank and the amount of his per capita assessment forwarded with the stub receipt. His name could then be included in the next monthly report from the state secretary to the General Secretary.

4. A most important practical point is that of pro-rating the dues of members joining during the year. If the state per capita assessment is $2.00 and a new member is admitted to the county society in June or July, should he be required to pay the entire amount of the state assessment? Or, should the state assessment be pro-rated for the unexpired portion of the year? While at first thought, it may seem unjust to ask a member to pay the year's assessment for half a year's membership, it seems best, for practical considerations, not to prorate the dues. The state per capita assessment is levied on each member for the expenses of the state society during the year and each member should pay his share, regardless of when he becomes a member. The plan of pro-rating involves a number of difficulties in bookkeeping and constant calculating as to the exact amount due from each society, as well as from each member.

5. Methods of Registration and Reporting.—During the past winter, letters were sent to many fraternal, benevolent, and labor organizations, asking for copies of all blanks, reports, etc., used by the secretary of the national body in his dealings with state and local organizations.

The secretaries of these bodies responded most cordially to the request for information and sent in a large amount of material, which has been gone over carefully with a view to securing suggestions from other organizations that would be of value to us. From all of the available material, the following plan is submitted for criticism:

COUNTY SOCIETY RECORDS

The American Medical Association can prepare books of blanks. [*This sample form is omitted from* THE JOURNAL. *In the Handbook for the House of Delegates it showed the two sides of the blank, the private postal card being the back of the individual member's pocket card, and the small blank headed "This side for state secretary's use" being the back of the middle stub headed "State Secretary."*] These blanks are planned to print on standard size cardboard stock, so as to trim without loss and would be of the size and shape shown on the proof. They comprise: 1. Combination individual pocket card and receipt for each member, filled out and signed by the county secretary as the member pays his dues. This blank is both a receipt and a membership card and has on the back a private mailing card blank so that the secretary can detach it, address it to the member, place a one-cent stamp thereon and mail it without having to write a letter. The card is of convenient size to go in a pocketbook and can be retained by the member during the year as evidence of membership. The pocket card plan is used not only by the American Medical Association but also by the Chicago Medical Society, St. Louis Medical Society, Indiana State Medical Association, and a number of others. It has the advantage of giving the member tangible evidence of membership and of the fact that he has paid his dues. The amount of the state per capita assessment is printed in so that it will be the same in all counties in the same state and is added to the amount of the local society dues which vary in different counties. These blanks can be put up in books of 25, 50, 75 and 100 for use in county societies of various sizes and will constitute practically all the books which the county secretary will need to keep. When a member pays his dues, this card will be filled out and given to him. At the same time, the stub for the state secretary will be filled out and the third stub which will be bound into the book, will be retained by the county secretary. A glance at this book will consequently show in every case how many members have paid their dues for the current year and who these members are. It will also show how many assessments have been forwarded to the state secretary and how many are still to be sent him. By looking over the stubs, the secretary can tell in a few minutes just how much has been paid him for dues during the current year or the total footings can be carried forward on the back of each stub.

One of the most essential features of any plan of membership regulations is that it admit of easy and positive identification both of the individual and of the society through which he holds his membership. To accomplish these two points, the following plan is suggested:

(a) Blank receipt books for different years to bear a letter of identification which will appear on all of the blanks, as: 1911(A), 1912(B), 1913(C), etc. The single letters of the alphabet will thus provide for the next twenty-six years. At the expiration of that period, a new combination can easily be devised, as: 1938(XA), 1939(XB), 1940(XC), etc., thus enabling the blank for the current year to be identified at once.

(b) All blanks printed by the Association for county societies can be given a series of numbers corresponding approximately to the number of members in the state, a sufficient margin being left for all possible additions for the year.

By attaching a numbering device to the press on which these cards are printed, the number can be printed at the same time and can be automatically changed with each blank. In preparing these books, the secretary of the Illinois State Medical Society, for instance, would be notified that number 12,001 to 20,000 had been reserved for his state and would be asked to specify how many receipt books his county societies would need, indicating the number of books of 25, 50, 75, or 100 cards. Each member on paying his dues would receive a pocket card, which pocket card would bear the letter for the year and the serial number for his county and state. For instance, a member paying his dues in Chicago would receive pocket card (A) 13,527. The same serial number would appear on the stub sent to the state secretary and on the stub retained by the county secretary. A record would be kept in the General Secretary's office of the books sent out. If, now, the Chicago member holding the above card should go to California or Florida for his health and if any question should be raised regarding his membership, he would be called on to report the number of his pocket card. If he said he held pocket card (A) 13,527, it would indicate at once that he held his membership in Cook County and in Illinois and had paid his dues for the current year and was consequently a member in good standing. It would furthermore serve as a positive means of identifying the individual in California or Florida with the individual who had formerly been in Chicago. It would also afford a constant check both for the state secretary and the General Secretary on the county society membership.

At the end of the year, each county secretary would return his receipt book to the state secretary. The number of pocket cards remaining intact and the number of stubs would show at once whether the reports of the county secretary were correct or not and would also afford the state secretary a further check on the county secretary's report. After checking up these stubs, the book could, if necessary, be forwarded to the General Secretary's office and would serve as a further check on the General Secretary's records.

6. Compensation for County Secretaries.

Probably the weakest point in our organization to-day is that the county secretary, the executive officer of the organization which is the foundation of the entire body, is in most of cases, not compensated, and is consequently asked to do work at a considerable sacrifice. Practically all successful fraternal, benevolent, and labor organizations have an arrangement by which local secretaries are paid, either by the local organization or by the general society. Most of the county societies at present only collect a sufficient amount of dues from members to pay the annual running expenses of the society, and as much of the clerical work demanded of the secretary is for the benefit of the state and national organizations, it would probably be difficult to secure the adoption of any uniform law for the compensation of county secretaries by the county society. The following suggestion is therefore submitted for the consideration of the House of Delegates: Each county secretary at the end of the year to return the book of stubs and unused receipts to the state secretary as suggested above, the state secretary to check them up and forward them to the general Secretary of the American Medical Association. Each secretary who returns his check book to receive as compensation from the American Medical Association, 25 cents per member, to be remitted as soon as the stub book is received and verified.

Adoption of the plan outlined above would be entirely voluntary with each state society. If it wished to adopt such a plan, it could do so; if it preferred to retain its own plan, it could do so, but the general conduct of the organization would be along the lines outlined above and the majority of state associations would probably soon find that it was more convenient to conform to the uniform plan than to retain individual variations thereof. County secretaries would only be compensated in case the state society adopted the proposed plan and in case they sent in their reports at the end of the year. Probably for several years, only a part of the state associations would adopt it. Even if eventually all the state associations with an aggregate membership of 70,000 were to adopt such a plan, the total expense involved would amount to only about $17,500, while the resulting gain in business methods, postage, stenographer and clerk hire, loss through unpaid dues, disaffected members, etc., would far more than make up this amount as far as the entire organization is concerned.

STATE ASSOCIATIONS

The secretary of the state association would receive on the first of April (?) a report from each county secretary enclosing the stub for each member who had paid his dues up to date. These stubs could either be arranged as an index or the names could be transferred to a separate card index, as the state secretary saw fit. From all the county society reports, a complete roster of members for the year could then be made up, a copy of which could then be forwarded to the General Secretary when completed. Additional members joining from time to time, could be reported by the stubs, accompanied in each case by the per capita assessment.

OFFICES OF SECRETARY AND TREASURER TO BE UNITED

It has been suggested by a number of members of the Committee that an essential and important reform should be inaugurated as far as county society officers are concerned, in combining the offices of secretary and treasurer. Uniting these two positions will obviate the necessity of keeping two sets of records, as well as the possibility of errors through transmitting names from one official to another. The average county society has a membership of 34. To handle the business affairs of a body of this size certainly does not require two officers and there is no reason why the time of two men should be employed when on man can look after the business affairs of the society more effectively. Exception to this might be made in some of the large city societies where the work is heavier but in probably 95 per cent. of county societies a single officer is sufficient for these two positions.

The question of recommending the union of secretary and treasurer for state associations has also been raised and is submitted for consideration. Is there any practical necessity of having two officers, generally located in different towns with two sets of records? Could not the business affairs of the state association be better transacted by one man, with a saving of expense and labor?

RECOMMENDATIONS

Your committee realizes the importance of the work assigned to it and the impossibility at this time of presenting a final report on the many and complex matters before it for consideration. Constructive work in any organization is necessarily and advisedly slow. This is especially the case when distance and other duties make it practically impossible for the committee to meet and when all the work must be done by correspondence. Your committee makes the following recommendations:

(1) That the committee be continued and that the president be authorized to appoint active secretaries in place of those who have retired, if he deems this advisable.

(2) That the recommendations regarding disciplining of members if approved by the House of Delegates, be transmitted to the secretaries of the various state associations and that they be also printed in the *American Medical Association Bulletin* and the attention of county societies be called to them.

(3) That the committee be instructed to submit its recommendations regarding the uniform regulation of membership to the secretary of each constituent state association for criticisms and further suggestions, and that the committee be further instructed to submit to the House of Delegates at the 1911 session a complete system for the use of county and state societies and the American Medical Association for the regulation of membership, including all blanks, forms, files and regulations needed to put the proposed plan in operation, for the further consideration of the House of Delegates.

(4.) That the committee be instructed to revise the standard constitutions for county and state societies in accordance with the constitution and by-laws of the American Medical Association as adopted at this session. Respectfully submitted,

Thomas McDavitt, Chairman,
Walter R. Steiner,
J. H. J. Upham,
B. R. Schenck,
A. W. McAlester, Jr.,
I. C. Chase,
Frederick R. Green, Secretary.

Report of Committee on United States Pharmacopeia

To the Board of Trustees of the American Medical Association:

Your committee on the Pharmacopeia reports as follows:

The U. S. Pharmacopeia is at present the exclusive property of the United States Pharmacopeial Convention; it is the privilege of this convention and of this alone to determine what the Pharmacopeia shall be. The convention is composed of representatives from the medical and pharmaceutical professions; about two-thirds of those eligible under the present constitution belong to the former and one-third to the latter. It seemed to your committee that the most useful work the committee could do would be to collect information which would be of assistance to the medical delegates to the convention. The phase of the Pharmacopeial Revision in which the medical profession is chiefly interested is the scope of the book, and there has been an almost unanimous expression of opinion to the effect that the medical delegates should, to a large extent, determine this, and the Chairman of the Committee on Revision for 1900-1910 has formally requested the American Medical Association to prepare lists of drugs for admission to or deletion from the U. S. P.

In view of the many drugs of interest chiefly to practitioners in certain fields it was believed that the most valuable information as to admissions would be obtained from members of the various sections of the American Medical Association. Accordingly each Section of the Association was requested to appoint a committee on the Pharmacopeia. Five of the committees, those of the Sections on Practice of Medicine, on Ophthalmology, on Stomatology, on Pathology and Physiology and on Obstetrics and Diseases of Women have reported; the reports have been published and commented on in The Journal of the American Medical Association (Sept. 4, 1909, pp. 791, 793, 796; Oct. 30, 1909, pp. 1491, 1500; April 23, 1910, p. 1389 and April 30, 1910, p. 1457). Similar reports by the Sections on Dermatology, Laryngology and Otology, and Nervous and Mental Diseases, and probably from other Sections also, will be presented at the St. Louis session and will then be available for the Committee on Revision.

It was believed that much valuable information could also be obtained from the professors of materia medica and therapeutics and pharmacology in the medical schools entitled to representation in the convention. About 50 per cent. of all the delegates to the convention and about 75 per cent. of the medical delegates are appointed by the medical schools and no one connected with these is in such a favorable position to speak as to the wishes of the schools as are these professors. A letter was therefore addressed to them with the request that they express an opinion not only on the general principles to be followed in revising the Pharmacopeia but also on the desirability of retaining each of the 957 titles in the present Pharmacopeia.

Replies were received from all parts of the United States. Many of those replying stated that they had prepared their replies only after extensive consultation with their colleagues and alumni, careful examination of hospital records, etc. It is believed that these replies represent accurately the present attitude of medical schools toward the Pharmacopeia, and as the medical schools have, according to the present constitution of the Pharmacopeial Convention, a larger ownership in the Pharmacopeia than any other group of members, it is believed that these replies merit very careful consideration on the part of the convention. From 131 replies received the following figures were obtained:

S TO FUNCTION

Should the Pharmacopeia of the United States be a book of minimum standards designed *mainly* for the regulation of commerce in drugs and chemicals and the restriction of adulteration and fraud?

Yes—17. *No—54.* *Uncertain—4.*

Or should the Pharmacopeia be a compilation of acceptable standards for desirable medicaments and designed, primarily, for the protection of the public health?

Yes—98. *No—5.* *Uncertain—4.*

SCOPE

Should the Pharmacopeia embody standards for all of the 50,000 or more drugs and preparations that have been or are used as medicine for man or other animals?

Yes—2. *No—84.* *Uncertain—3.*

Or should the Pharmacopeia include all of the widely used drugs and preparations, irrespective of their medicinal value, and thus practically all of the titles now found in the U. S. P., the N. F., and the present edition of N. N. R.?

Yes—1. *No—83.* *Uncertain—3.*

Or should the Pharmacopeia continue to be, as is at present attempted, the standard for medicaments of recognized value and established use and, therefore, be restricted rather than extended in number of titles?

Yes—102. *No—2.* *Uncertain—4.*

GENERAL PRINCIPLES TO GOVERN ADMISSIONS AND DELETIONS

Should drugs that possess no well-recognized medicinal value be included in the Pharmacopeia?

Yes—5. *No—106.* *Uncertain—9.*

Should the duplication of drugs having essentially the same medicinal action be encouraged?

Yes—21. *No—93.* *Uncertain—15.*

When the medicinal properties of a drug are fully represented by an active principle, should both the drug and the active principle be retained?

Yes—35. *No—48.* *Uncertain—26.*

Should substances that are largely affected by commercial conditions, such as foods (figs and prunes, for example) and beverages (brandy and whisky, for example), be retained in the list of pharmaceutical articles?

Yes—8. *No—83.* *Uncertain—20.*

Should substances that have no direct therapeutic value and are primarily used as solvents or reagents be relegated to the Appendix?

Yes—113. *No—7.* *Uncertain—9.*

Should the now frequent duplication of pharmaceutical preparations, such as wines, vinegars, syrups, tinctures, and fluidextracts of the same drug, be discouraged?

Yes—104. *No—12.* *Uncertain—13.*

Should fixed formulas for mixtures be discouraged?

Yes—85. *No—30.* *Uncertain—13.*

Should all formulas for preparations that can be made extemporaneously be deleted from the Pharmacopeia?

Yes—75. *No—38.* *Uncertain—15.*

Should all complex preparations be relegated to the National Formulary, and the Pharmacopeia itself retained as a standard for simples and simple preparations?

Yes—92. *No—23.* *Uncertain—12.*

Should the Pharmacopeia endeavor to comply with well-established international nomenclature and standards for drugs and preparations?

Yes—125. *No—0.* *Uncertain—2.*

Should compounds or mixtures that are permanently controlled, either by secrecy or proprietary rights, be admitted to the Pharmacopeia?

Yes—7. *No—104.* *Uncertain—5.*

Should the Pharmacopeia be the accepted standard for medicinal prescribing?

Yes—120. *No—1.* *Uncertain—5.*

Has it been your experience that, in the eyes of medical students and practitioners, Pharmacopeial recognition of a drug implies, in a general way, an endorsement of its usefulness in therapeutics?

Yes—87. *No—29.* *Uncertain—8.*

Of the articles now contained in the Pharmacopeia practically no objections were made to the following:

There were a number of preparations, including several recently introduced into the Pharmacopeia, on which many did not express a direct opinion.

The committee did not deem it wise to make specific recommendations as to the revision of the Pharmacopeia except to express the opinion that if the recommendation of the Board of Trustees of the Pharmacopeial Convention that an advisory Committee on Revision of fifty be selected is approved, the latter should be composed equally of delegates from medical and pharmaceutical organizations and that the nominating committee should be instructed to submit the names of 25 medical and of 25 pharmaceutical delegates; such a request seems reasonable in view of the fact that about two-thirds of the organizations entitled to representation in the convention are medical organizations.

Respectfully submitted.

George Dock.
Robert A. Hatcher.
Reid Hunt.
Edward E. Hyde.
W. S. Thayer.

Exceptions:—Dr. S. Solis Cohen takes "exception to the form of the questions on the scope of the Pharmacopeia, especially the last question, because the 'therefore' which is included in that question does not follow" and also because "the question of basic drugs is one thing and the question of preparations included in the N. F., etc., quite another." He also thinks "a large proportion of the uncertain answers received on this [there were 3 uncertain and 84 positive answers.—Chairman] and other questions is due to the bad form of the questions." He also takes exception to the form of the question relating to the admission of "compounds or mixtures that are permanently controlled either by secrecy or proprietary rights" considering it to be "doubly misleading in that it confounds compounds and mixtures (concerning one of which the answer might be 'yes' and the other 'no'); and again confusing secrecy and proprietorship (concerning one of which the answer could only be 'no,' while concerning the other there is considerable room for debate, and an honest 'yes' would doubtless be given by many who have answered 'no' to the full question, were this particular issue separated). The question if separated would in part read: 'Should drugs having a definite and known chemical composition, but monopolized by virtue of patent rights, be excluded from the Pharmacopeia?' This question has not been put distinctly from other issues, and therefore has not been answered." [The question related only to *permanently* controlled articles; the question of articles controlled by "patent rights" in which the proprietorship is limited, was not raised.—Chairman.]

The newly elected officers of sections are given in this issu in the General News Department.

Society Proceedings

AMERICAN GYNECOLOGICAL ASSOCIATION

Thirty-fifth Annual Meeting, held in Washington, D. C., May 3-5, 1910

(Concluded from page 1995)

Fibroid Tumor Complicating Pregnancy and Rendering Natural Labor Impossible

Dr. B. F. Baer, Philadelphia: Early in my medical career I saw two cases of pregnancy complicated with fibroid tumor, in one of which rupture of the uterus occurred during labor, followed by death of both the mother and child. In the other case, death resulted from septic peritonitis in consequence of injury of the soft parts following instrumentation for dystocia caused by complicating fibroid. The child perished during the labor. The first patient was attended by a midwife. In the other case I was an assistant. This experience impressed on me the fact that pregnancy complicated with fibroid tumor was a most serious condition. I will report briefly six cases. The first was one of multiple fibroid tumor of the uterus complicating pregnancy, with hemorrhage and miscarriage; myomectomy and oöphorectomy; recovery. In the second, I resorted to supravaginal hysterectomy for fibroid tumor complicating pregnancy and rendering labor impossible; recovery. The third case was one of fibroid tumor complicating pregnancy, hemorrhage and miscarriage, in which supravaginal hysterectomy was done; recovery. In the fourth, a fibroid tumor in the posterior wall of the uterus complicated pregnancy. Pelvic incarceration rendered the continuance of pregnancy dangerous and labor impossible, and supravaginal hysterectomy was done at the fifth month, followed by recovery. In the fifth, pregnancy was complicated with fibroid and ovarian tumor; supravaginal hysterectomy was done, followed by recovery. In the sixth case, pregnancy was complicated with fibroid tumor in the lower zone and broad ligament, blocking the pelvis and rendering natural labor impossible. Abdominal hysterectomy was done at the seventh month; recovery. These cases show the importance of operating on tumors interfering with the natural delivery of the child.

DISCUSSION

Dr. I. S. Stone, Washington, D. C.: A distinction ought to be made between the disappearance and reduction in size of fibroids. I do not believe in the disappearance of fibroids unless degeneration sets in, or unless necrosis takes place and a submucous abscess forms and discharges. A fibroid may disappear in that way or by twisting of the pedicle, getting separated from the uterus and disappearing. But I take no stock in the idea that fibroids will disappear after pregnancy.

---

[1] Also recommended for deletion by Section Committees of the American Medical Association.

Dr. Charles M. Green, Boston: In one case I found the pelvis of a woman filled with a fibroid tumor, so that nothing else could be felt. During transmission to the hospital the fibroid pulled out of the pelvis, and when I saw the woman I could reach the os and found a breech presentation. I gave her further time, the fibroid ascended out of the way, the woman was delivered of a living child, and made a normal convalescence. When she became pregnant again I watched her through pregnancy, and nothing occurred in the size of the fibroid. She went through that pregnancy, delivered herself and there was no perceptible increase in the fibroid.

Dr. Edward Reynolds, Boston: Two or three years ago I saw a young pregnant woman with a fibroid in the uterus. She miscarried. I determined the position of the fibroid with fingers inside the uterus and hand outside. I operated on her for other causes about a year ago, and found at the site of the fibroid no tumor whatsoever, but a white, comparatively bloodless area in the uterine wall, which evidently represented complete disappearance of the tumor. I do not believe such cases are exceptionally rare. In the general question of fibroids during pregnancy, we should discriminate carefully between fibroids of the fundus and fibroids in the lower segment of the uterus. Fibroids of the fundus, especially if pedunculated, can be removed safely during pregnancy and complicate labor comparatively little.

Dr. Willis E. Ford, Utica, N. Y.: I have one very remarkable case to report of a girl whom I saw before her marriage with an intramural fibroid which reached half way up to the umbilicus. I was called to see her after marriage when she was pregnant at the fifth month. This was 14 years ago. I got ready to do a Porro operation. Fortunately nothing happened. She was delivered in the normal way. The other day I examined her and found that this fibroid tumor has entirely disappeared, as far as I am able to judge.

Dr. Richard C. Norris, Philadelphia: I have seen tumors situated in the lower segment of the uterus retract themselves, these tumors being drawn out of the way by the action of the longitudinal fibers, and disappear when I was about ready to perform Cesarean section, and the woman be delivered spontaneously. It is my conviction that myomectomy should be more restricted during pregnancy than at other times.

Dr. George T. Harrison, New York: It is well known that in negro women myomata are much more common than in those of the white race. The exhaustive paper of Hofmeier demonstrates conclusively that the position of a myoma is not a bar to conception, and the proof is found among the negro race. A number of years ago I reported a case in which myomectomy was performed on a woman when she was several months pregnant, and she was carried to full term. A fibroid tumor had grown in the meantime in the pelvis which necessitated Cesarean section, followed by hysterectomy; unfortunately the woman had sepsis and died from it.

Dr. B. F. Baer: If a woman has a fibroid complicating pregnancy, and she has not borne any children, but desires to have one child, she should have that privilege, and pregnancy allowed to go on in the presence of the fibroid, but it is our duty to advise her as to the dangers of this fibroid.

Extrauterine Pregnancy of Eleven Months

Dr. E. C. Dudley, Chicago: I operated in this case July 20, 1909, two months after term. The mass was posterior and to the left of the uterus. The incision was made in the median line. The tumor was almost universally fixed by adhesions or by continuity of development. The adhesions were intestinal, uterine, parietal, and omental; in fact, they existed between the mass and all adjacent structures, especially to the anterior abdominal wall and the sigmoid flexure. The mass, about eleven inches in diameter, was separated from its adhesions and shelled out unruptured. The resulting raw surfaces were equal approximately to a surface not less than twelve inches square. An incision was made back of the uterus into the posterior vaginal fornix, and through this incision a continuous gauze drain was introduced from above downward into the vagina. The upper part of this drain consisted of gauze packing sufficient to fill the field of operation and to prevent oozing. This packing was then covered in by stitching together the peritoneal surfaces above it in such a way as to cut off completely the field of operation from the remaining portion of the abdominal cavity, and to cover all with normal peritoneum. This suturing across the pelvis from side to side involved extensively intestinal structures, and especially the sigmoid flexure, which was stitched to omental, parietal, bladder and other visceral peritoneum wherever possible to bring the parts together in order to quarantine the field of operation from the general peritoneum. The abdominal wound was closed without drain and healed promptly. A slight fecal fistula subsequently discharged through the vagina, but closed spontaneously in a few days. Such extensive enucleation of so large a mass due to ectopic pregnancy ordinarily would not be undertaken. The fact that success followed this operation does not necessarily influence me in recommending the procedure as a routine in similar cases. I report the method with the suggestion that it might be considered more surgical than the conventional operation of incision and drainage, but although more surgical, it perhaps may with subsequent experience prove to be more dangerous.

DISCUSSION

Dr. Edwin B. Cragin, New York: I have operated in four cases of ectopic gestation at full term. Two of the women were delivered of living children at the operation. The question of operation revolves around the point whether the sac and its contents shall be removed at the single sitting, or the sac opened and the cavity drained. In one of the four cases I was able to ligate the vessels supplying it and able to enucleate the sac, but was obliged to take the uterus with it. This gave me primary union of the abdominal wall, without drainage, and a short convalescence. It is exceptional, judging from my small experience, that one can with safety ligate the nutrient vessels and remove the sac *en masse*. In the other three patients the placenta was adherent to the structures at the floor of the pelvis, and to have attempted to ligate the vessels supplying the placental sac would have killed the woman. In these three cases a wiser procedure was to leave the sac open, to separate the placenta gradually, and then let the wound heal by granulation. This was done. All the patients recovered, but this was only one of the four cases in which I was able to follow anything like the procedure reported by Dr. Dudley of complete enucleation.

Dr. E. E. Montgomery, Philadelphia: About fifteen years ago I operated on a woman, who was 15 months pregnant. The uterus was in front of the sac. After opening the abdomen it was found that the small intestines were so intimately related to the sac that it was impossible to attempt its removal. We removed the fetus, and made a communication between the sac and the abdominal wall, and packed with iodoform gauze. While the patient had a stormy convalescence, she recovered.

Dr. Herman J. Boldt, New York: I do not believe that one can lay down a hard and fast rule as to the procedure which must be pursued in any given case. I have had four cases of ectopic gestation at or near term, and in only one instance was it possible to remove the sac without rupture. In the others I resorted to a procedure similar to that described by Dr. Cragin. I lost one case.

Dr. A. Lapthorn Smith, Montreal: I have had two cases of tubal pregnancy at term. One of the women refused operation and is alive to-day. In the other I removed the child, and when I attempted to enucleate the sac the hemorrhage was so profuse that I stopped, and closed the wound. While she had no rise of temperature, she died in eight days from exhaustion. I would favor leaving the placenta in cases in which profuse hemorrhage is likely to follow its removal. One of my colleagues attempted to remove the placenta in such a case and the woman died on the table from hemorrhage.

Dr. E. W. Cushing, Boston: I had one of these cases many years ago in which I waited until the child died. It seemed a safer thing to wait about a month, which I did, then opened the abdomen. The sac was thin, and the child was found loose in the abdominal cavity. The woman recovered without trouble.

Dr. G. B. Miller, Washington, D. C.: About five years ago I had a case of ectopic gestation in which I operated, delivering a living child at term. The placenta was attached to the tube and broad ligament, with firm pedicle, so that it was easily removed. The sac was adherent over the anterior abdominal wall and to the omentum which gave rise to some hemorrhage. The whole sac with placenta was removed, and the woman recovered. The child unfortunately died of hemorrhage following ligation of the cord by the nurse, to whom the baby was turned over at the time of the operation.

Dr. Joseph Taber Johnson, Washington, D. C.: I had a case of ectopic gestation about ten years ago. The woman was supposed by those who saw her before I did to be twelve months pregnant. The nature of the case was not clearly understood and at the operation doubt was expressed as to whether there was pregnancy or not, but there was a large tumor on the side of the uterus. This was enucleated without breaking the sac, which was found to contain a full-grown fetus, weighing nine pounds. The abdomen was closed without drainage, as there was nothing to drain. The patient made a good recovery.

Report on Vaccine Therapy in Gynecology and Obstetrics

Dr. J. Whitridge Williams, Baltimore; Dr. Edwin B. Cragin, New York, and Dr. Franklin S. Newell, Boston, constituted the committee that made this report. The evidence at present available seems to justify the following tentative conclusions concerning the value of vaccine therapy in gynecology and obstetrics:

1. Opsonins undoubtedly play a part in the production of active immunity. On the other hand, the determination of the opsonic index is technically very difficult, and is subject to such variations that it is not available as a diagnostic or prognostic guide, and even among trained bacteriologists there is considerable skepticism as to its practical value.

2. Immunization by means of vaccines is a well-established prophylactic measure against certain infectious diseases, notably typhoid, cholera, plague and dysentery. Vaccine therapy is undoubtedly a valuable remedial agent in local infections due to the tubercle bacillus or staphylococcus, less so in local infections due to other pathogenic bacteria, while there is considerable doubt as to its efficiency in acute general infections.

3. In chronic gonorrheal arthritis and urethritis it is a valuable adjunct to other treatment, and occasionally may lead to cure alone. It appears to be useless in the acute infections, while it is more efficient in the treatment of vulvovaginitis of children than any other means, but even here it does not always result in cure.

4. In infections of the urinary tract, especially those due to the colon bacillus, it sometimes results in symptomatic cure, but rarely relieves the bacteriuria. The scanty reports concerning the pyelitis and the pyelonephritis of pregnancy indicate that vaccine therapy is no more efficient than the usual treatment by rest in bed and the administration of salol or hexamethylenamin, as in neither does the bacteriuria disappear until after the termination of pregnancy.

5. In certain cases of endometritis it appears to reinforce the curative influence of curettage. The reports concerning its use in pelvic inflammatory diseases are too scanty to justify conclusions, but it would seem that it may be of value only in chronic postoperative cases with sluggish fistula formation.

6. As the ordinary localized puerperal infections, irrespective of the nature of the offending bacteria, tend to spontaneous cure, the field for vaccine therapy is practically limited to acute general infections, whereas they unfortunately appear to be of little value, and the most that can be said from the reports thus far available is that their employment does no harm.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

How "National Leagues" are Organized

The following editorial from the Joliet (Ill.) *Weekly News* is interesting in connection with the recent campaign of newspaper advertising and spasmodic publicity directed against the public health bill introduced by Senator Owen. No doubt many of the names of the so-called "directors" of the local organizations inspired by this league have been secured through misrepresentation or without the signers knowing the significance of the organization which they were endorsing:

PUBLIC HEALTH

A surprising opposition to the proposed department of public health is being sprung on the congressmen. At first the source of the many letters and telegrams was unknown, but later developments revealed that it is a concerted effort on the part of the new schools of medicine or healing—osteopaths, mental healers, Christian scientists and other enthusiastic opponents of regular medicine.

Those who make a discovery in healing, though it is but a cure for a boil or a sore thumb, become very enthusiastic and apply their method to every form of affliction from consumption to a broken neck, and are impatient with those who hold to other methods. It is not only so in medicine, but it is true of all lines of skill and science. The new brooms are enthusiastic.

A young man came to the *News* office recently and asked the editor to join in a movement for public economy, the curtailment of extravagance, abolition of graft, but being somewhat interested in those lines for a number of years, and believing that present methods were doing at least something, the editor held aloof. The young man added this postscript: "Well, to be frank about this matter, I suppose this organization has a purpose to defeat the movement for a department of public health now before congress. You know it provides another place for politicians and grafters."

"Now, surely, I cannot see my way clear to join your lodge," said the editor. "For many years I have felt that our greatest waste in natural resources was the waste of the man himself. With all of our present-day knowledge and boastful enterprise, we permit people to run these streets afflicted with diseases more deadly than leprosy. We permit conditions in public conveyances that scatter other contagious diseases. We eat tainted food and drink tuberculous milk, and, in short, waste human life more than we have wasted our forests or soil.

"At this office we are thorough believers in the preservation of our natural resources, our forests, streams and soil, and believe in their improvement, but above all we believe in the preservation and improvement of man himself. For years we believed there was something wrong in the plan of government that permitted these things and we looked to the general government for a remedy. We need the aid of the government to check the bubonic plague. For ten years, San Francisco, with the assistance of the government, has held the plague at bay. The government discovered the source of yellow fever and malaria and now it is after the hook worm and pellagra. The government is doing well, but it should do better.

"Young man, when you came to the *News* office with a scheme to defeat the government in the greatest work of the century, you got into the wrong box."

Senator Owen's Speech on the Public Health Bill

The *Congressional Record* for May 25 contains a short statement made by Senator Robert L. Owen on that day in the United States Senate regarding the public health bill. Senator Owen's statement is so concise and conclusive that it is printed entire for the information of those of our readers who may not have access to the *Congressional Record*. The attack through the newspapers of the country of the Owen bill on the ground that it has any bearing whatever on the licensure of physicians can be the result only of ignorance or mendacity, since any intelligent person knows that the licensing of physicians, like the regulation of any profession or trade, is a function of the state and cannot possibly be assumed by the national government. Equally foolish was the statement made before the Senate Committee on Public Health by one Frederick A. Bangs, who stated that he represented the "Voters and Tax-Payers' Association," which organization under questions from the committee proved to have been organized in the last ten days for the sole purpose of opposing the Owen bill. Mr. Bangs said that "behind this bill lies the power of the United States, if it is passed, to compel them (the people) to take any kind of medicine the regular doctors may insist that they shall take." Following this surprisingly illuminating statement, Senator Martin, chairman of the committee, said, "I am amazed that any intelligent man would intimate for a moment that there is anything in this bill that would compel anybody to take any medicine at all." Such was the exhibition of ignorance before the committee on the part of the opponents of the bill that its chances of passage have been greatly improved by the last hearing.

Senator Owen's speech follows:

DEPARTMENT OF PUBLIC HEALTH

Mr. President, I have been amazed, and I suppose that every Senator on this floor has been, to receive many telegrams from "homeopaths," "osteopaths," "eclectics," "chiropractics," and practitioners and believers in Christian Science and suggestive therapeutics, and from other good citizens, protesting against a department of public health apparently on the unfounded notion that the bill introduced by me (S. 6049) proposed or made possible some interference by the federal government with the practice of medicine and constituted a possible invasion of the medical freedom of the citizen to employ whom he pleased when sick. None of the protests point out the language of the bill by which this could possibly happen, and for the obvious reason that no such language exists in the bill. None of these protests suggest any amendment to correct either an error of omission or commission in the bill. They simply protest against an interference with the medical freedom of the citizen, with which the bill contemplates no interference, with which the federal statutes cannot interfere within any state.

I understand that during the last week a large number of so-called "taxpayers' and voters'" associations have been organized with many members in several states of the union for the purpose of opposing a department of public health.

I am informed that the sudden and surprising interest of the "taxpayers and voters" of the United States who are organized in this artificial manner and the active interest alleged or manifested of the "homeopaths" and of the "osteopaths" and of the "eclectics" and of the great variety of those who have special views with regard to the various methods of healing the sick has taken place within seven days, and like a flash of lightning telegrams are coming in from Maine to California. The chairman of the Committee on Public Health and National Quarantine of the senate received a very large number of them. Such sudden universality of disapproval of a department of public health on such an unsound theory is astounding; it is more, it is extremely suspicious; it is obviously artificial; it is perfectly apparent that somebody is spending a very large amount of money on this sudden propaganda; it can hardly be doubted that somebody, in gross error, is advising the "homeopaths," the "osteopaths," the "eclectics" that their right to practice medicine is about to be invaded by the federal *government*.

The agency through which this propaganda is being carried on against a department of public health is carrying the flag of "medical freedom."

And an active and authorized representative of this organization in the *Washington Post* is quoted as saying (Friday morning, May 20, 1910):

> I believe the creation of a federal department of health would mean the abridgment of long-cherished rights of the people, which would mean the taking away of the enjoyment of one of the most sacred rights for which man has had to contend—the right to select the practitioner of his choice in the hour of sickness. If such a bill became law, hundreds of practitioners would be thrown out of practice, men who have succeeded in curing persons who have been given up by physicians. It would particularly affect Christian Science healers and osteopaths. In their line, both *these classes* of practitioners undoubtedly have done a world of good, and they should not by unfair legislation be outlawed. It should make no difference whether we believe in Christian Science, osteopathy or any other practice, the people should have the privilege of choosing their own practitioners. They should not be prohibited from so doing by legislation.

This is an astonishing and utterly impossible interpretation of the bill which I introduced in the senate of the United States proposing a department of public health.

The bill itself merely brings the various bureaus affecting the public health in one body, under one head, without changing the character of the activities or authorities of such existing bureaus, to wit:

> All departments and bureaus belonging to any department (excepting the army and navy) affecting the medical, surgical, biological, or sanitary service, or any questions relative thereto, shall be combined in one department.

The greatest of these bureaus dealing with the public health is the Bureau of Public Health and Marine-Hospital Service, but various public hospitals, the Bureau of Chemistry and of pure foods and drugs, and bureau of meat inspection, including some 16 laboratories of the federal government, are to be transferred to one department by this proposed bill.

Nobody has heretofore protested against the existence of these bureaus or their functions.

Nobody has declared them unconstitutional.

Nobody has charged that they in any wise have interfered with the homeopaths, osteopaths, eclectics, Christian Scientists, or any other school of healing.

Nobody has contended that they would do so, or has desired that they should be abolished for fear that they would interfere with the local practitioners in the gentle art of healing.

No man who has any knowledge of constitutional law would believe it possible that the federal government could invade the police powers of the state, or in any way interfere with the liberties of the citizen or of the local practitioner.

The Supreme Court has repeatedly passed on this question, and held that the states, under their police powers, exclusively control such matters. All lawyers are familiar with these principles. The leading cases I insert in the *Record* for the convenience of those who may not be familiar with the matter:

> United States, *v.* De Witt (9 Wall., 41); Slaughterhouse cases (16 Wall., 36); United States *v.* Reese (92 U. S., 214); United States *v.* Cruikshank (92 U. S., 542); Munn *v.* Illinois (94 U. S., 113); Civil Rights case (19 U. S., 3).

All citizens know that the states exclusively control the issuance of licenses to practice medicine.

Nobody ever heard of the federal government considering such a matter or pretending to have any interest in it.

Every member of the Senate and the House of Representatives knows that the federal government has nothing to do with the local practitioner or the hostilities which may exist between different schools of medicine, if any such do exist.

I wish, however, to put in the *Record* my assurances to the members of the medical profession, of whatever school of healing, a few facts which I trust may abate any apprehension on this score.

First. Senate bill 6049, proposing a department of public health, was drawn by me without the knowledge of any school of medicine or of any medical association. I was greatly pleased to find that many members of the various medical schools and associations, including homeopaths and eclectics, approved the bill.

I have been pleased to observe the wholesale cordial support of osteopaths and men of all schools of healing for a department of public health. The bill contains no provision either directly or indirectly interfering with any school of healing, whether osteopaths, homeopaths, eclectics, Christian Scientists, or in those who reject all medicine. It could not accomplish such a purpose if it had the intent, as the federal government has no such police powers within the state, the states alone issuing licenses to control the practice of medicine and religious and personal freedom being a constitutional right in which everybody believes.

As the author of this bill I wish to say that I believe the more a man knows about the laws of health the less drugs he takes. I have employed homeopaths and osteopaths and allopaths as well to treat myself and the members of my family. I have studied the doctrine of suggestive therapeutics and of Christian Science with great interest and respect, and cordially indorse Horace Fletcher as the best doctor of them all. I stand firmly for medical freedom and for the right of the citizen to select his own medical or spiritual adviser.

The department of health, proposed by me, has for its object the prevention of sickness, and therefore taking business away from all doctors.

The members of the profession whose hearts are constantly wrung by the grief and sorrow at the bedside of sickness and death naturally desire to prevent bad health and illness, even if it be to their financial loss, as it evidently is, and every member of the noblest of professions will stand for the department of health when its purposes and its constitutional limitations are well understood.

The absurd theory that any medical association could, by any possibility, take charge of the health activities of the government of the United States and interfere with the medical freedom either of citizen or practitioner is preposterous.

It is to the honor of all the members of this sympathetic and self-sacrificing profession that they are so largely interested in preventing disease and thus diminishing the need for their own employment. All disciples of every school of healing, I should think, should engage in a generous rivalry to put an end to disease and prevent tuberculosis, typhoid and yellow fevers, bubonic plague, pneumonia, and the many diseases which are known to be preventable.

This is about all a department of health can hope to assist in, and it can only do this by cooperating with the states on constitutional lines in educating the people on the elementary laws of health and well-ascertained facts relating to the prevention of the wholesale sickness and death of our people.

It is beyond belief that any of our good citizens engaged in curing the sick would seriously oppose the reasonable exercise of either the state or national activities within their constitutional limits for the prevention of the illness and death of our people.

Medicolegal

Doctrine of Privileged Communications—Commenting on Not Calling Physician as Witness Not Allowed—Definition of "Physician"—Persons Not Prohibited from Making Disclosures

The Supreme Court of Indiana says, in William Laurie Co. vs. McCullough (90 N. E. R. 1014), a personal injury case brought by the latter party, that it is provided by the Indiana statute that: "The following persons shall not be competent witnesses. . . . Fourth. Physicians, as to matter communicated to them as such by patients, in the course of their professional business, or advice given in such cases." The statute was designed to subserve the good of society, and to promote a full disclosure of all facts and conditions necessary to a correct diagnosis and proper treatment of human ailments, by securing the patient against involuntary disclosure of information given in confidence. The prohibition of the statute is absolute in its terms, yet its provisions were made for the protection of the patient, and the privilege of secrecy granted may be waived by the one directly concerned. It is manifest that in many instances the physician may acquire, by virtue of his office, only such information as might, with propriety and without embarrassment to the patient, be published to the world; while in other cases a disclosure would be revolting to the sensibilities of the public, and injuriously affect the business and social standing of the patient in the community, without any countervailing good results. It is obvious, therefore, that the patient may with good reasons be clothed with a discretion to waive the privilege of secrecy. The purposes of this statute are broader than the exigencies of any given lawsuit, and in the legislative judgment the considerations of public policy and general advantage to mankind from the establishment of inviolable confidence between physician and patient outweigh the private interests of any particular litigant.

In electing not to call his physician as a witness it is clear that a party may have motives and potent reasons in no way involving the suppression of evidence prejudicial to his interests in the case on trial. The law grants to a patient the unqualified right to exclude the testimony of his physician as to facts acquired in confidence, and the exercise of this privilege cannot be impaired by allowing opposing counsel in argument to impugn his motives or charge him with suppressing important and relevant evidence. The general rule, authorizing an inference from withholding of important and material evidence on the matter in issue, that such evidence if heard would be prejudicial to the cause of the party having it in his power to produce the same has no application to privileged communication which the law excludes on ground of public policy. The court in this case properly denied counsel for the defendant company the right to comment on the plaintiff's failure to call a physician, who had treated her, as a witness in her behalf, and in directing the jury to disregard the statement made on the subject, when in the course of his argument to the jury he asked why did she not have the physician there to testify, if she did not have curvature of the spine. The holding in the case of City of Warsaw vs. Fisher, 24 Ind. App. 46, to the effect that adverse counsel have a right to comment on the failure of a party to avail himself of the testimony of his physician is disapproved.

But, prior to the time of receiving the injuries for which she sued in this case, the plaintiff, on the advice of a physician, took treatment, consisting of gymnastic exercises, of a superintendent of a gymnasium and orthopedic institute. The defendant introduced him as a witness, and offered to prove by him that he knew of the plaintiff's physical deformity and infirmities, both from his own examination and from what she told him while under his care. The superintendent had never applied for or received a physician's license, and was not a physician as defined by the Indiana statute. The offered evidence was excluded as privileged under the provisions first quoted, excluding physicians as witnesses "as to matter communicated to them, as such, by patients, in the course of their professional business." This was error. "The word 'physician' is defined to mean a person who has received the degree of doctor of medicine from an incorporated institution; one lawfully engaged in the practice of medicine." 30 Cyc. 1544. It is made unlawful for any one to practice medicine in Indiana without first obtaining a license so to do; and practicing medicine without license is punishable as a misdemeanor. Information gained by a physician while in attendance on his patient was not privileged at common law, and the state statute, being in derogation of the common law, is not to be enlarged by intendment. It manifestly relates to general practitioners and those only whose business as a whole comes fairly within the definition of "physician." By the terms of the statute in some of the states the ban of secrecy is extended only to information given to persons "authorized" to practice physic or surgery; but, as we have seen, the word "physician" includes those only who are "lawfully" engaged in the practice of medicine, and therefore duly authorized to pursue that vocation. This is the sense in which it is used in the Indiana statute. It will not be presumed that this exceptional privilege was intended to apply to transactions between citizens and charlatans or impostors, whose business is conducted in violation of the law, nor can it be extended by construction to persons employing other curative processes not coming within the ordinary meaning of the term "practicing medicine."

It has been held that a statute prohibiting any person authorized to practice physics or surgery from disclosing any information acquired while attending in his professional character had no application to dentists, or to a druggist furnishing medicines to a person applying for the same, or to a veterinary surgeon. The statute of Colorado excludes the testimony of physicians authorized under the laws of that state, and the evidence of physicians authorized to practice in another state was held competent. The New York courts hold that when a party seeks to exclude evidence under a statute similar to that of Indiana, the burden is on him to bring the case within its purview. The superintendent referred to was not a "physician" within the meaning of that word as used in the Indiana statute under consideration, and made no claim to be such, and the information which he acquired while giving the plaintiff a course in gymnastic exercises was not privileged.

Death of Injured Hay-Fever Patient Right After Administration of Antitetanus Serum

The Supreme Court of Minnesota says, in the case of Gardner vs. United Surety Co. (125 N. W. R. 264), that the insured, while in a stable, was kicked by a horse. His thigh was cut, and the evidence indicated that he was thrown and struck his head against some part of the barn. After the accident he appeared to be in great distress, and a physician was summoned, who, after dressing the wound, suggested, as stables were fruitful breeding places of tetanus germs, it might be well to administer an injection of antitetanus serum, although expressing the opinion that there was not one chance in a million that tetanus would ensue. The man consented, and toward the evening of the following day the physician injected the serum. Immediately after the man was seized with a fit of sneezing, and died within a few minutes. A postmortem examination disclosed that his lungs and bronchial tubes had been completely filled through regurgitation. It also disclosed some injury to the head, which it was claimed was severe enough to have produced concussion of the brain.

The beneficiary suing to recover the insurance, which was against injuries through "external, violent and accidental means," introduced evidence tending to support her claim that the injury received was sufficient to cause a shock, impairing the nervous system to such an extent that the regurgitation of the contents of the stomach ensued, causing death by suffocation, and, further, that the injection of the serum was the proper treatment indicated after the accident, and, even if such treatment caused the filling of the lungs, death was still by suffocation, of which the accident was the proximate cause. The company, on the other hand, contended that death resulted solely from the injection of the serum, which treatment was not necessarily indicated by the injury received, but was at most because of a possible infection of the wound which the attending physician deemed it prudent to guard against; that such treatment was improperly administered to the insured, who was afflicted with hay fever, and that the injection of the serum was the proximate cause of the death, and was not external, violent or accidental within the meaning of the policy.

The court does not agree with the contention that death from suffocation is in every case, except where such result is intended, to be regarded as produced by external, violent and accidental means. But the appeal must be determined by considering whether the injuries received were the proximate cause of death on the following day; that is, was the administration of the serum an independent supervening cause of death, or was it to be considered one of the possibilities within the contemplation of the parties at the time the contract of insurance was entered into? The parties contemplated that the individual injured would act as an ordinary normal person, and that a physician would be called, whose judgment would be relied on for the treatment to be administered; and where, as in this case, a reputable member of the medical profession was called, and his treatment was regular, ordinary, and in accordance with the teachings of his profession, there can, it seems to the court, be no escape from the conclusion that the treatment administered was a natural and anticipated result of such injury, and that although death might not have resulted, had no injection of serum been made, the original injury, confessedly received under conditions within the terms of the policy contract, must be held to be the proximate cause of death.

The evidence did not conclusively show that, even if the insured was afflicted with the disease known as "hay fever," the injection of the serum would be fatal; and it followed that the jury were properly instructed that the plaintiff was entitled to recover if the treatment given was rendered necessary and proper by the injuries, and that death resulted solely from the injuries and the injection of the serum.

9 Enumeration of Spermatozoids. A. L. Benedict, Buffalo.

1. **The Nervous System and Skin Disease.**—Fordyce summarizes the rôle of the nervous system in the production of skin diseases by the statement that from the higher centers in the brain to the peripheral distribution of the nerves the skin may reflect circulatory or trophic disturbances some of which are typical and others only suggestive of a relationship. In the one case the etiologic factor is single and specific and in the other the rôle of a nervous influence is only contributory in a complicated causation which our present knowledge does not permit us to interpret in an exact manner.

The nervous system is directly concerned in sensory disturbances, as the hyperesthesias, anesthesias, and paresthesias. The posterior root ganglia and their analogues the Gasserian and geniculate ganglia, together with the peripheral nerves are concerned with the most characteristic skin lesions due to primary nerve involvement. Next to these are the skin lesions of syringomyelia, the changes which follow disease of the peripheral nerves in leprosy, and other forms of neuritis, or after division, partial or complete, of nerve trunks.

The nervous system may act as a predisposing or contributory cause in eczema, dermatitis herpetiformis, lichen planus, pemphigus, etc., by lowering the nerve tone. Psychic shock, mental strain from anxiety, grief or overwork are states which are often invoked in such conditions.

Hysteria leads to self-mutilation—the so-called feigned eruption—sensory disturbances, and possibly to spontaneous bullous affections and gangrene. The nervous system through the sympathetic, the adrenals and other chromaffin tissue related to the sympathetic, may be concerned in pigmentary and leucodermatous changes.

3. **Glycyl-Tryptophan Test.**—The authors applied the test in 21 cases in 11 of which the value of the test was shown at operation. In 5 of these 11 cases the test was negative, although the clinical history was positive, and at operation the stomach was found normal, the carcinoma or other condition being situated elsewhere. Of the remaining 10 cases, not operated, 3 gave a positive test. Two were cases of pernicious anemia and one was a case with stomach symptoms, which was lost sight of. In two cases diagnosed as carcinoma and two of possible carcinoma, the test was negative. In a case of cerebral syphilis, one of neurasthenia and one with stomach symptoms the test was negative. A repeated negative reaction is regarded as most valuable. However, when the test is positive, the complication of a regurgitation of trypsin must be thoroughly investigated.

12 The Therapeutic Value of Lactic Acid Bacteria. L. S. Medalia, Boston.
13 *Treatment of Emphysematous Gangrene Due to *Bacillus Aerogenes Capsulatus*. R. H. Gilpatrick, Boston.

10. **Graves' Disease.**—Mumford reviews both the medical and surgical methods of treatment and summarizes his article as follows: 1. Graves' disease is due to abnormal activity of the thyroid gland; 2, in advanced Graves' disease, degenerative changes in the thyroid gland may lead to a shifting symptom-complex ending at last in the positive signs of myxedema; 3. the histology of the gland in Graves' disease indicates shifting, advancing and retrograding symptoms; 4, an enlarged thymus is nearly always found post-mortem in patients dead of Graves' disease; 5, advanced Graves' disease may exist without the presence of all the classical symptoms; 6, Graves' disease can nearly always be cured if taken early; 7, the sera of Rogers and Beebe cure a goodly percentage of cases; 8, through hydrobromate of quinin (neutral), as used by Forchheimer and by Jackson, a large percentage of improvements and of cures was found; it is a pity so few cases have been reported; 9, the great and increasing experience of qualified operators is showing that more than 70 per cent. of Graves' disease patients are now being cured by partial thyroidectomy, and the percentage of such cures is rising; 10, treat the cases seen early by rest, by sera and by hydrobromate of quinin; if no improvement results in two months, operate by thyroidectomy, and always regard the operation as the surest one.

13. **Emphysematous Gangrene Due to Bacillus Aerogenes Capsulatus.**—After a review of the literature, Gilpatrick gives his experience with lactic acid milk and draws the following conclusions: 1. Lactic acid milk when prepared at home from tablets is unreliable as to taste and bacterial contents. 2. The objection to the use of the tablets in their dry state is their unreliable bacterial content, the loss of viability of organisms in their dry form, and the high price. 3. Buttermilk, pure and simple, when obtained from the dairyman, varies considerably as to taste (at times very sour, sometimes bitter) and bacterial content and is, therefore, unreliable. It is also deprived of the principal nourishing elements of milk. (The buttermilk as obtained from the dairyman is a side product with him, is the watery fluid left after churning the butter and as such probably not much attention is paid to its keeping, handling, etc.) 4. The Bulgarian lactic acid bacillus (*B. bulgaricus* so highly recommended by Metchnikoff produces too much acid, which taste is not tolerated by most patients. For this reason Metchnikoff is advocating now the use of the paralactic organism mixed with the *B. bulgaricus* in order to obtain a better tasting soured milk. Which of these two organisms is responsible for the good results cannot be definitely determined, as the *B. bulgaricus* does not grow readily at room tempera-

ture and is, therefore, outgrown by the paralacticus, which grows most readily at room temperature. It might be safe to say that the beneficial results are apparently due to the latter. 5. A good, clean soured milk can be obtained by means of any lactic acid organism in pure culture implanted in sterilized but not boiled milk. The palatability, however, being an important factor, makes it necessary to choose the organism best suited for this purpose. 6. The therapeutic value of soured milk depends chiefly on the lactic acid organisms it contains as well as on the fact of its being a good food article, and not on any particular kind or variety of the lactic acid organism. Any clean, palatable milk properly soured would answer the purpose. 7. A good tasting buttermilk can be prepared at home from sterilized milk with a "starter" of lactic acid organisms. One starter will last for several weeks or months if the directions for the preparation described in the article are carefully followed. A new starter should be obtained on the first sign of contamination detected in taste or in change in the manner of curdling. 8. The *B. bulgaricus* in pure culture in dextrose bouillon as a therapeutic application in infectious processes, although of benefit in certain conditions as a good local antiseptic, is not a cure-all and must be used with caution. In the oral cavity it should be used with great care, if at all, because the action of the lactic acid on the enamel may give rise to caries. 9. Public safety demands that the various buttermilks or soured milks in the market should be thoroughly inspected by the health and pure food authorities.

cian' is defined to mean a perso[illegible]

tainly a marked advantage. Foster's preference for material used is either medium-sized linen or intestinal silk. The needles should be very small, with a tri-cutting edge point and a short curve. The suture should be about sixteen inches in length, with a needle threaded at each end, the thread secured by a single knot. One of the needles is passed through the mesenteriolum as near the proximal end of the appendix as possible. This suture is then tied, while the assistant holds the attached hemostat in the left hand and lifts the free margin of the meso-appendix, by the aid of tissue forceps, held in the right hand. Following the tying of this suture, the assistant releases the mesenteriolum from the tissue forceps, still keeping the appendix taut by the use of the hemostat in the left hand. The operator then gently grasps the suture in his left hand and with scissors in his right hand cuts the appendix loose from its meso-attachment. Near the base a dry sponge replaces the scissors and the appendix is easily freed fom all meso-attachment. The appendix crusher is then applied to the base of the appendix and after removal of the former the latter is firmly tied with a No. 2 chromic catgut, thus preventing any bleeding from this locality. A fine pointed artery forceps is then made to grasp this catgut ligature as near the appendix as possible, the loose end of the ligature being cut off close to the artery forcep. The needle on one end of the linen suture is then passed just beneath the artery on the meso side of the base of the appendix. The needle is then turned in the opposite direction and encircles one-half of the cecum base about half an inch distant from the base of the appendix, picking up the peritoneal covering of the cecum at intervals of a quarter of an inch until a point is reached on the other side of the appendix, just opposite the meso-attachment. The needle on the other free end of the linen suture encircles the peritoneal covering of the cecum in the same way, but on the opposite side of the appendix base. This part of the suture is continued until it meets and just overrides the end of the half of the same suture coming from the other side. The appendix base is surrounded by a clean, dry sponge and the former crushed twice just above the catgut ligature. The appendix is then amputated, the assistant supporting the stump by the artery forcep attached to the catgut ligature. The appendix stump may be cauterized or not, according to the will of the operator, after which the sponge is removed. The assistant inverts the appendix stump by the use of the hemostat attached to the catgut ligature, while the operator ties the linen suture. Just before the linen suture is completely tightened the assistant loosens the hemostat and withdraws the same, leaving the appendix stump well buried. A second knot is then tied in the linen suture and the latter cut. The operation is then completed, except for closing the abdominal wall incision.

63. **The Influenza Bacillus in the Respiratory Tract.**—Holt holds that the use of the term influenza should be limited to an inflammation or infection excited by Pfeiffer's bacillus. It is of great importance in all infections of the lower respiratory tract, especially during the cold weather. It has very much less to do with acute nasopharyngeal catarrhs and their complications, otitis, adenitis, etc. It may cause severe general symptoms with few or no local symptoms, even of the respiratory tract; but general blood infection with this organism is very rare. While in most patients the influenza infection causes acute symptoms only, recurrences are exceedingly common, and in some patients the attacks are prolonged, persisting for months. The *B. influenzæ* may be harbored in the secretions of apparently healthy persons for a considerable period, certainly for several weeks; whether such persons may spread the disease is not yet determined. If properly made, cultures are of great value for diagnosis, but the bronchial secretion should be secured.

64. **Clinical Estimation of Pepsin.**—In the Jacoby-Solms method the stomach contents are not neutralized, the estimations are not made under like conditions of acidity. Rose has modified the method in this respect and makes all digestions in a solution whose total acidity is 0.2 per cent. of hydrochloric acid. By this means one determines, not the digestive power of the gastric fluid, but the relative amount of pepsin present. The necessity of knowing whether or not the gastric juice in question is normal in respect to acid before diluting is also avoided.

66. **Blood-Pressure in Epidemic Meningitis.**—Robinson found that heightened intracranial tension appears to be an almost constant phenomenon in epidemic cerebrospinal meningitis. Heightened blood-pressure of a moderate degree, he says, is not infrequently seen in the early acute stage of the disease, when exacerbations of symptoms occur, late in the disease, or when the malady takes on a chronic aspect. The blood-pressure seems to bear some relation to the severity of the disease, being higher when the symptoms are severe, and low during convalescence. The withdrawal of cerebrospinal fluid by lumbar puncture has no constant effect on the blood-pressure, although there is usually a fall of blood-pressure synchronous with this procedure. Robinson concludes that his series of observations affords no definite evidence that heightened intracranial tension causes an increased blood-pressure in meningitis, unless it is late in the disease, when internal hydrocephalus may develop as a result of blocking of the foramina of the fourth ventricle.

68. **Paratyphoid Cholecystitis.**—Interesting features in connection with Cecil's case are the following: (1) The absence of a history of typhoid or paratyphoid fever. Two hypotheses may be advanced in explanation of this: The attack of fever was a very mild one or the case was one of primary paratyphoid infection of the gall-bladder. The marked agglutinative power of the patient's serum. In a dilution of 1/200 there was complete agglutination of her own organism at the end of one hour. The agglutinations were also specific, the serum having little or no effect on the typhoid or paratyphoid bacillus, Type B, but acting readily on other strains of the A type. The agglutination reactions were also positive and specific in the other cases of paratyphoid cholecystitis, to which he has already referred. No paratyphoid bacilli were found in the feces when it was examined 17 days after the operation. Unfortunately no examination was made before the operation or immediately after it. The patient, however, had most probably been a paratyphoid carrier.

75 Meningitis Complicating Pneumonia. A. Hymanson, New York.

74. **Rheumatism of Childhood.**—Clemens has frequently noticed the enlargement of the thyroid gland in the rheumatic diseases of childhood and now claims for it a place as a sign of rheumatism in the rheumatic series. The time when the thyroid enlargement was first noticed varied. In some cases thyroid enlargement preceded all other manifest signs of rheumatism. Again it has appeared as the fourth or fifth link in the rheumatic chain, and at other times it has been found to persist in association with chronic endocarditis after all other rheumatic manifestations have disappeared. The degree of enlargement of the thyroid gland, while not great, is sufficiently pronounced to give an unnatural fulness to the neck when inspected from the front. When viewed laterally the sharp contour of the gland is unmistakable.

88 *The Diagnostic Value of the "Hemolytic Test" in Cancer and Tuberculosis. F. Smithies, Ann Arbor.

88. **Hemolysis.**—The results of Smithies' work comprise observations on 158 cases affected with various ailments and clinically well. The summary shows that of the 158 cases, 26, or 16.4 per cent., revealed positive reaction. Of these 26 cases more than half were cases of malignant disease. The majority of the remainder were syphilitic and tuberculous. The disease conditions generally giving positive reaction were those associated with more or less marked anemia, and in many instances with loss of weight. Of the 158 cases tested, 94, or about 60 per cent., were negative, while 27, or about 17 per cent., were classed as undetermined. Some of these so classed might have been called positive by a more experienced worker. Eleven cases showed "reverse hemolysis." The greater number of these were tuberculous—moderately advanced cases with anemia—but a fair proportion of "reverse hemolysis" was obtained in the cases of malignant disease. Certain facts are brought forward prominently. It seems that in the blood serum of some cases of malignant disease—those generally associated with anemia and loss of weight—there exists a hemolytic property for alien red cells. It also appears that

while this phase is interesting and may be of value in certain individual cases, similar manifestations are possible from the sera of patients non-cancerous. It will be noted, however, that the conditions where this direct hemolysis is obtained are those frequently associated with anemia, loss of weight and cachexia. The reaction of reverse hemolysis mentioned by Crile as occurring in 92 per cent. of cases of tuberculosis is characteristic. It occurs occasionally, but is by no means characteristic inasmuch as it also occurs in malignant disease, syphilis and other diseases.

6 Cultural Characteristics of the Microbacillus of Acne. E. H. Molesworth.
7 Achondroplasia. O. Eichholz.
8 General Suppurative Peritonitis: Recovery. H. Cooper.

3. **Gastrostaxis.**—According to Bolton the evidence that gastrostaxis exists is threefold, namely: (1), that at certain post-mortem examinations of patients who have died of hematemesis no lesion has been found in the stomach to account for the bleeding; (2), that at certain operations performed on such patients, an ulcer has not been found; (3), that gastrostaxis possesses a definite clinical history. However, the natural conclusions to which one is driven from a consideration of the condition is that gastrostaxis, as an independent disease, is not yet indisputably proved to exist; and on the other hand, that acute gastric ulcer is a most important and very common malady, and one which is worthy of more consideration than appears to be given to it.

4. **Implantation of Ureters.**—Knaggs reports a case of inveterate vesicovaginal fistula in which the left ureter was implanted and the right kidney removed successfully. One year after the operation the patient was alive and well.

15 *Desiccated Culture Media. E. T. Thompson.
16 The Aims of Medical Education. A. C. Geddes.

12. **Maternity Cases in Liverpool Workhouse Hospital.**—The total number of women admitted during 1907, 1908 and 1909 was 1,330; married, 761; single, 539; primiparæ, 455. Residing in the workhouse for variable times before confinement. 382; admitted direct from town when in labor, 926; admitted from the workhouse lock ward, 22. Of maternal mortality there were six cases due to nephritis, phthisis, pneumonia, syncope and signs of edema of the lungs, sepsis, abscess found in broad ligaments, pus in uterus, probably previous pyosalpinx and eclampsia. Infantile mortality: Mature, dying soon after birth, 22; mature, stillborn, 15; premature and immature, 78; premature and decomposed, 82. Of the mature, the causes of death were debility, cyanosis, syphilis and apnea, but in most of the cases debility was the cause. Of the mothers admitted during 1909, 19 had suffered or were suffering from syphilis. In 6 cases syphilis was suspected, but the grounds for suspicion were not conclusive. Children born: males, 704; females, 653; twins, 27. Presentations: head, 1,272; transverse, 11; breech, 46; knee, 1; foot, 23; face, 4; shoulder, 1; and with cord, 17. Operations: forceps, 57; versions (podalic), 14. Complications: eclampsia, 3; albuminuria, 32; pneumonia, 4; hemorrhage, 45 (accidental 26, unavoidable 15, postpartum 4); adherent placenta, 4; adherent membranes, 5; retained placenta, 1; ophthalmia in infants, 13 (neonatorum 4, catarrhal 9).

14. **Treatment of Spasmodic Asthma.**—Melland claims that the effects from the treatment of the paroxysms of asthma by the hypodermic injection of epinephrin is marvelous. He gives only one injection, 10 minims of a 1 in 1,000 solution. The injection may be repeated if other attacks supervene.

15. **Desiccated Culture Media.**—The preparation of small quantities of culture media is always a tedious process and usually attended with unsatisfactory results. It occurred to Thompson that many of the culture media might be dried and reduced to a powder containing all the requisite solid constituents which would remain indefinitely in an unaltered condition. The culture media under investigation were nutrient gelatin, nutrient agar-agar, nutrient beef broth, and MacConkey's neutral-red bile-salt lactose-agar. These were all evaporated to dryness and when made up to their original volumes with distilled water and dissolved at 100 C., were quite clear, the gelatin, the agar-agar and bile-salt-agar solidifying with their original firmness on cooling. The reaction of the broth before drying, which was + 15 acid to phenolphthalein, remained unaltered after treatment. The agar-agar, gelatin, and broth were each distributed into test-tubes and sterilized; they were then inoculated with several of the pathogenic, saprophytic and chromogenic bacteria, respectively, and without exception vigorous and typical growths were obtained.

The neutral-red bile-salt-agar was distributed in Petri dishes and allowed to dry in the usual manner and then inoculated on the surface with a mixture of *B. typhosus*, *B. coli*, *B. subtilis*, and *B. megatherium* by means of a bent glass rod. No difficulty was experienced in rubbing the surface with the glass rod; in fact, the rubbing was performed a little more vigorously than necessary in order to test the texture of the medium, but it remained unbroken. After 48 hours incubation at 40 C., typical colonies of *B. coli* and *B. typhosus* had developed, the coli colonies being red and the typhoid colonies being colorless. The *B. subtilis* and *B. megatherium* had not grown. Thompson claims that these experiments show that the typical reactions may be obtained with this medium after desiccation and that its inhibitory properties are in no way impaired.

29 *Clinical Diagnosis of Cancer of the Testicle. M. Chevassu.

May 18, No. 40, pp. 369-376

30 *Duration of Chronic Nephritis. G. Schreiber.

28. **Treatment of Genital Prolapse by Bridging the Vagina.**—Juvara has applied Le Fort's technic in six cases, the patients all elderly women, and he comments on the simplicity and ease of the technic and the very satisfactory results. He gives ten illustrations of the technic and the outcome in a typical case. The flaps are taken from the front and rear walls of the vagina, the outer edges sutured together, bridging it across and making the lumen smaller, forming a solid support, at the same time leaving a space each side of the bridge for escape of secretions.

29. **Cancer of the Testicle.**—Chevassu reviews the early manifestations of malignant disease in the testicle as he has encountered them in a number of cases. In one case there was merely a slight increase in the size of the gland, the lower two-thirds were abnormally hard and tender with slight irregularity of the surface at the rear. In 3 other cases the testicle was the size of a large egg, the surface smooth or slightly knobby, the consistency elastic and fluctuating or harder above and elastic below, with tenderness above or below, the spermatic cord apparently normal or a little larger and less flexible than its mate. In all these cases the diagnosis long wavered between hematocele, syphilis and cancer of the testicle, until examination of the epididymis showed that this was still intact, which confirmed the assumption of cancer. With other lesions the epididymis is almost certain to be early involved. When hesitating between the diagnosis of hematocele and cancer, he adds, it is well to bear in mind that the chances are nine to one in favor of the latter. A syphilitic lesion may simulate cancer of the testicle, but specific treatment soon clears up the diagnosis. If no benefit is derived from a week of daily mercurial injections, operative treatment is indicated without further delay. In the first case the cancer was removed in an early stage with every prospect of complete cure, but the patient, a young soldier, succumbed in 18 months to glandular metastasis in the abdomen. This and similar experiences suggest the necessity for systematic removal of the aortico-lumbar glands as the indispensable supplement to castration for malignant tumor in the testicle.

30. **Duration of Chronic Nephritis.**—In the case reported the patient, a woman of 62, developed mitral stenosis after acute rheumatism at the age of 20; this was followed five years later by symptoms of nephritis from lead poisoning. Albuminuria persisted for 33 years before serious symptoms from the nephritis developed, although there was no attempt at restriction of the diet during these years. Schreiber cites a number of instances on record in which the nephritis existed in a continuously latent form for many years, the patient surviving after differentiation of the disease for from 20 to 43 years. Such cases suggest that strict dietetic measures are not always necessary for patients with mild chronic nephritis.

39 *Chronic Primary Progressive Polyarthritis in Children. J. Stargardter.

33. **Physiology of Infant Nutrition.**—Schlossmann thinks that in striving to avoid overfeeding of infants physicians are apt to go to the other extreme, and the result is an *atrophia e medico*, unless the mothers supplement the ordered ration. He protests against determining the proper amounts by comparison with the weight, saying that this leads to erroneous conclusions; the surface area, rather than the weight, should be considered, and when this is done, it is seen that the progress of the child—as evidenced by the elimination of carbon dioxid and consumption of oxygen—parallels the increase in surface area. He tabulates the details in a number of cases, and also emphasizes the importance of refraining from giving too much fluid on account of the danger of demineralization from continued excessive intake of water; it requires unnecessary expenditure of energy, taxing the heart, kidneys, etc., to pass it through the body and eliminate it. No more fluid should be given than corresponds to that of breast feeding.

39. **Chronic Primary Progressive Polyarthritis in Children.**—All the articles in this number of the *Archiv* issue from Schlossmann's clinic for children's diseases at Düsseldorf. Stargardter closes the list with a case of this rare disease. The patient was a child, a little over 10, who lived in a damp house. The joint affection developed at the age of three but no acute phase was ever observed. The joints showed nodular enlargement at various points. By the age of 10 the jaws, spine, right hip and shoulders were the only joints not affected. The trouble was insidious and progressive and the muscles showed extreme atrophy. No benefit was derived from any treatment. Stargardter has found 66 other cases on record in children from 2 months to 14 years old. He discusses the differentiation and the unfavorable prognosis, and remarks in conclusion that the etiology of the disease is as obscure as treatment is powerless.

47 Specific Characteristics of Milk Albuminoids. (Artcharakter der Milcheiweisskörper.) J. Bauer.
48 Latest Experiences and Views on Scalp Diseases. (Trichophytieerkrankungen.) C. Bruhns.

40. **Omentopexy.**—Credé has found about 120 cases in the literature in which the Talma operation has been performed during the twelve years since it was introduced in treatment of ascites from obstruction of the reflux of blood through the portal vein. Ascites of other origin is scarcely amenable to this measure, although there is a case on record of cure from it in malarial splenomegaly and in a case of Banti's disease. The number of cures in the total 120 cases is only 40 and the cure proved permanent in only 20. He discusses the cause of so many failures with this logical and promising operation, and reports 5 cases in which he has applied it himself. The result in these cases has convinced him that the ordinary technic is not extensive enough and that greater benefit can be derived when the development of more and larger collateral vessels is insured. He accomplishes this by making a raw surface over the front of the greater omentum, over an area as large as the hand, snipping it with scissors, detaching the peritoneum from the muscles and then suturing; the procedure is thus more radical than Talma recommended. The outcome was a permanent cure in the case related in detail; the ascites has not recurred since the operation, six months ago, although previously up to 11 liters of fluid had been withdrawn at a time and the patient had required frequent tapping.

43. **Action of Cod Liver Oil in Rachitis and Spasmophilia.**—Rosenstern reports from the children's asylum at Berlin in charge of Finkelstein that extensive experience is confirming the specific curative action of cod liver oil in rachitis. In 5 cases with pronounced craniotabes, of which the details are tabulated, remarkable benefit followed administration of 25 gm. of cod liver oil daily for three to six weeks. In the spasmophilic diathesis cod liver oil also displayed marked efficacy. The results were so conclusive that Rosenstern affirms that this method of treatment may be counted on to cure in the majority of cases of spasmophilia, especially when phosphorus is combined with the cod liver oil. Phosphorus in ordinary oil or in an emulsion displayed no influence on the spasmophilia. His dosage is 0.01 part phosphorus to 250 parts of cod liver oil for the severest cases, a teaspoonful five times a day. Cod liver oil without phosphorus seems to have the same effect if given in larger doses. The clinical research reported confirms in every respect Schabad's conclusions, based on study of the metabolism, in regard to the specific action of cod liver oil on rachitis and spasmophilia. Rosenstern estimates the severity of the rachitis by the extent of the craniotabes, representing it by a square that comprises the extreme limits of the softening of the bones, noting how this square grows smaller during the course of the cod liver oil treatment. The severity of the tendency to convulsions or allied phenomena—spasmophilia—is estimated by the electric irritability of the nerves, especially the cathodal opening contraction. This is proving a very accurate index of the severity of the spasmophilic diathesis, especially when the response is compared with the Chvostek sign and other spasms.

Deutsche medizinische Wochenschrift, Berlin

56 *The Pain of Deforming Arthritis. P. Ewald.
57 Edible Clays in Therapeutics. (Essbare Erden und ihre Verwendung als Heilmittel.) Martini and Grothe.

51. **Operative Treatment of Spastic Diplegia.**—Hevesi has applied Foerster's operation, that is, resection of the roots of the posterior spinal nerves, in a very severe case of Little's disease and the surprising benefit confirms all that Foerster claims for the operation. Nature herself points the way to treatment in this line; when tabes develops during disturbances due to interruption in the course of the pyramidal tracts, all the symptoms of exaggerated reflex excitability vanish at one stroke. This is the result of interrupting the reflex arc, and in case of imperfect development of the pyramidal tracts all that is necessary is to sever the connection by resection of the posterior roots. Hevesi's patient was a child of 11 who had never been able to walk without aid. After laminectomy and resection of the posterior lumbosacral spinal roots, 3 or 4 on each side and each for from 2 to 6 cm., the wound healed by primary intention and by the seventh week the patient was able to walk alone. This rapid benefit surpasses even that reported by Foerster who did not commence exercises in standing or walking until after four months. No special sensory disturbances were noted nor ataxia. None of the other measures advocated for Little's disease attacks the true cause; this "rhizectomy" alone accomplishes.

53. **Psychic Causes of Mental Disturbances.**—Birnbaum comments on the way in which the assumption that emotions can develop psychoses is being more and more abandoned. Such causes are able to develop a psychosis only in peculiarly predisposed individuals, especially those of a hereditary degenerative type, and the forms of the psychosis are those that develop on this basis. The psychic impetus may be comparatively trifling.

56. **The Pain of Arthritis Deformans.**—Ewald insists that deforming arthritis may develop without infectious or toxic influences, purely from static disturbances, throwing the joint out of gear. A disturbance of this kind in the foot may react on a joint above, and many are the cases of supposed sciatica that have been cured merely by the use of a flat-foot insole. The joint affection does not cause pain until the synovial membrane becomes irritated, as he shows by three typical examples. The Roentgen rays may show lesions of deforming arthritis for years without pain or functional disturbance, but then pain may suddenly develop from some slight trauma to which a deformed joint is peculiarly exposed. The resulting synovitis causes pain and interferes with the use of the joint, and the inflammation is much harder to conquer than a similar disturbance in a previously sound joint. Weeks of massage and superheated air and passive exercises may be necessary before the patient can use the limb again. These measures do not influence materially the osteoarthritis but they restore the functional use of the limb. The process in the bones may exist without pain for years, but it prepares the soil for the later painful synovitis. He adds in conclusion that deforming arthritis after infectious processes and nervous arthropathies may possess a static factor, and the proliferating process may be regarded as reparatory in its nature.

Deutsche Zeitschrift für Chirurgie, Leipsic

April, CIV, Nos. 5-6, pp. 425-632

61 Case of Telangiectasia of the Tongue. H. Meerwein.
62 *Postoperative Psychoses. E. Schultze.
63 *Five Cases of Direct Transfusion of Whole Blood. (Ueber Bluttransfusion beim Menschen.) G. Hotz.

60. **Epinephrin in Collapse from Paralysis of the Vasomotor Center.**—Heidenhain quotes many authors to confirm his own experience that in case of collapse from weakness of the vasomotor center, such as is liable in pneumonia, diphtheria and peritonitis, good results may be obtained with a suprarenal preparation injected into a vein, or, diluted with salt solution, injected subcutaneously. In conclusion he reports a case of uncomplicated ileus in which by this means it proved possible to tide the apparently moribund patient past the danger stage after two days of fecal vomiting, and thus permitted a successful operation.

62. **Postoperative Psychoses.**—Schultze reports 12 cases of postoperative psychoses to emphasize the importance of auto-intoxication, inanition and weakness, feeble circulation, etc., as factors in the development of postoperative psychoses. Eliminate these factors and the psychoses become rare indeed. The practical conclusion is evident that every effort should be made to strengthen the patient before attempting the operation. *The prognosis is generally good; only a few of the patients on record were left with a permanent psychosis.* The nature of the operation seems immaterial. In all the cases the mental disturbance improved proportionately to the improvement in the physical condition.

63. **Direct Transfusion of Blood.**—Hotz reports five cases in which severe losses of blood were compensated by direct *transfusion of the whole blood from the artery of another* person sutured directly to the median vein of the patient. A near relative is the best for the purpose, as there is presumably less difference in the composition of the blood. The details of each case are given, the results on the whole being very encouraging.

Medizinische Klinik, Berlin

May 8, VI, No. 19, pp. 731-770

64 *So-called Muscular Rheumatism. A. Schmidt.
65 Spontaneous Gangrene in the Young. H. O. R. Schmiz.
66 Bismuth Intoxication. Windrath.

68 Influence of Sea Climate on the Blood Picture. (Einfluss des Seeklimas auf das Blutbild.) O. Hellwig.
69 Practical Importance of Geology for Balneology. A. Leppla.

64. **Treatment of Muscular Rheumatism.**—Schmidt is convinced that the pain in muscular rheumatism is of the nature of neuralgia, and he suggests treating it with injections of physiologic salt solution at the painful points. Peritz has advocated this, and Schmidt's own experience has confirmed the great benefit liable to be derived from injection of 5 or 10 c.c. directly into the muscle at the most painful points. This, he adds, is no etiologic treatment, for the seat of the trouble *is certainly not in the muscle itself, but it relieves the* pain and that is the main thing. In very old or especially violent acute cases he would not hesitate to do lumbar puncture, following with spinal anesthesia if necessary. Even the puncture alone has given great relief in some cases; in others the effect was only transient. He regards lumbar puncture as harmless under proper precautions, and thinks that a trial of it is justified in severe cases.

Monatsschrift für Geburtshülfe und Gynäkologie, Berlin

May, XXXI, No. 5, pp. 547-686

70 Origin of Accessory Mammae and Ductless Axillary Mammary Glands in Puerperæ. (Kasuistischer Beitrag zur Frage der Genese der Mammae accessoriae und der sogenannten Achselhöhlenbrüste ohne Warze und Ausführungsgang bei Wöchnerinnen.) A. Knaebel.

73 Transperitoneal and Extraperitoneal Cervical Cesarean Section: 15 Cases. (Zur Frage des suprasymphysären Kaiserschnittes.) M. Lange.
74 *Heating the Pelvis Through by Electric Means: Thermopenetration. (Die elektrische Durchwärmung des Beckens als Heilmittel.) H. Sellheim.
75 *Three Cases of Acute, Non-Puerperal Peritonitis in the Puerperium. (Drei Fälle von nichtpuerperaler, akuter Peritonitis im Wochenbett, durch Operation geheilt.) H. Kritzler.

74. **Thermopenetration.**—Sellheim describes the technic and results of the application of electricity to heat the pelvis evenly throughout. The technic for this thermopenetration, as it is called, permits the passage of the heat without injury of the parts in contact. One electrode is introduced into the vagina or rectum with the other electrode parallel on the abdomen above. By changing the position of the second electrode it is possible to send the heat through all parts of the pelvis. With a current of one ampere the region between the electrodes can be heated to a constant temperature of over 40 C. (104 F.); no by-effects were observed in any case.

75. **Non-Puerperal Acute Peritonitis in the Puerperium.**—In the three cases described the acute peritonitis was conquered by surgical measures as under other conditions. The peritonitis was due to torsion of an ovarian cyst in one case and to appendicitis in the others.

85 [illegible] the Lungs. W. Hildebrandt.
86 [illegible] rité Hospital at Berlin. (Aus der [illegible] *Krankenhauses zu Berlin.*) K. Sudhoff.

79. **Lymphocytosis in Exophthalmic Goiter.**—Bühler has examined 20 patients with pronounced exophthalmic goiter and 70 patients with an incomplete form of the disease, and found a relative lymphocytosis pronounced in nearly every case. He regards this as an important differential sign of a thyroid toxic origin for the symptoms observed. Examination of the blood thus may prove of great value in aiding in the differentiation of exophthalmic goiter, although negative findings are not conclusive.

80. **The Wassermann Reaction in Pseudoleukemia.**—Caan obtained positive findings in four cases of pseudoleukemia, although there was nothing to indicate syphilis in the antecedents. *These findings speak against the absolute specific* nature of the Wassermann reaction, while at the same time they suggest that the pseudoleukemia may be due to some spirochete action, possibly supplemented by other etiologic factors.

87. **Tests of Kidney Functioning.**—Blum reviews the basis for and the technic of various functional tests and their value for internal medicine and surgery. The sound kidney is able to adapt itself to varying demands within a wide range, and this is the basis of the dilution test which, he remarks, is the only means yet at our disposal for estimating the latent reserve force of the kidney. The patient drinks two or three glasses of mineral water, after which the ureters are catheterized and the onset, the amount and the duration of the polyuria thus induced determined; the change in the freezing-point is an index of the functional capacity of each kidney. He says in regard to the indigo-carmin test that this drug is eliminated by the kidneys alone, the sweat, saliva, bile and stools showing no trace of the stain; that it is non-toxic and harmless, and that it passes through the body without forming derivatives; it behaves like any other sodium salt and its elimination is analogous to the excretion of the urinary salts, so that this test is peculiarly important, as it approximates so closely physiologic conditons. (The technic was described in THE JOURNAL, Jan. 2, 1904, page 69.) He does not approve of the phloridzin test. It has been his experience that with old, chronic nephritis the difference between the kidneys does not surpass that under normal conditions. Parenchymatous disturbance interferes very slightly with elimination of water and salts.

88. **Natural Factors in the Healing of Tuberculosis.**—Tutsch has examined several hundred animals in respect to the size of the vital organs and has found that those species which are distinguished by greater resistance to tuberculosis are always those in which the heart, spleen and liver are *comparatively* much larger in proportion to the size of the animal than in other species. The richer the body in spleen and liver cells and the more oxyhemoglobin these cells produce, the more energetic the processes of oxidation in the body and the greater the resistance. The biochemical basis of natural immunity is thus the greater oxidation going on, and therapeutic and other measures to increase the oxidations are the natural, fundamental indications for treatment of tuberculosis.

92 *Study of 334 Cases of Hypertrophy of the Prostate. A. Götzl.
93 *Action of "*Prostate Toxin*" in Prostatitis and Incipient Hypertrophy of the Prostate. J. Sellei.

91. **Traumatic Hydronephrosis.**—Wildbolz reports a case of true traumatic hydronephrosis, the ureter having evidently been crushed by the accident, with resulting circumscribed necrosis and probably minute perforation. A small hematoma and collection of urine at the point gradually induced changes in the region, leading to compression of the ureter and the kidney above had to be removed. From his industrial insurance the man was allowed 30 per cent. indemnity for the assumed resulting impairment of his earning capacity, but Wildbolz remarks that this is scarcely enough. The Swiss authorities exclude from industrial insurance persons who have had one kidney removed. Any injury, even comparatively slight, of the remaining kidney is liable to prove fatal. When the collection of blood and urine is large and the process develops entirely outside the kidney, the resulting pseudohydronephrosis may be cured by shelling out the encapsulated collection or making a permanent fistula to drain the cyst. In two cases reported this was successfully done. One patient was a woman who had been trampled by a cow; in the other case the patient had slipped on ice and fell sitting. In the latter case the kidney had to be removed with the cyst, as the ureter had evidently been torn out by the accident. There were no severe disturbances at first. Not until after nearly a month were there attacks of pain. They resembled some attacks which she had had a few months before that had been attributed to an inguinal hernia and had subsided after the herniotomy. Their recurrence later suggested that the kidney had probably been responsible for them in the first place, and thus had not been sound at the time of the accident.

92. **Hypertrophy of the Prostate.**—Götzl reviews his experience with 334 cases of hypertrophy of the prostate. He operated in only 11 per cent. of the cases *on the prostate* alone, but in over 17 per cent. an operation was undertaken on account of complications. In 24 cases the patients were under the age of 50. He found it possible by hygienic and dietetic measures to keep the first phase of the hypertrophy stationary for many years. Cystitis heals entirely if the amount of residual urine is not excessive and if the bladder wall is sound. Under other conditions the cystitis persists, refractory to all measures, even when the mechanical obstacle has been removed. Stagnation of the residual urine was responsible for development of stones in 71 per cent. of his cases. With patients complaining of severe gastrointestinal disturbances, frequent thirst and desire to urinate, a prostatic affection in an advanced stage should always be suspected. He adds that the suprapubic operation is winning constantly more adherents while palliative operations are losing ground. He lost one patient from postoperative pulmonary embolism; Riedl has called attention to the peculiar liability to this with thrombosis in the prostatic region.

93. **Organotherapy in Prostatitis and Incipient Hypertrophy of the Prostate.**—Sellei reports surprisingly favorable results from injection of the patient's own or an alien prostatic secretion in the effort to induce a kind of immunization against abnormal conditions in the prostate. The resulting development of autoprostatotoxin or isoprostatotoxin seems to have a curative influence on prostatitis and incipient hypertrophy of the prostate. He also found it possible to enhance this action by injection of specific cytotoxic serum from "prostatics" given preliminary treatment of this kind, their serum evidently acquiring increased proportions of cytolysins. His article is based on experiences with 18 cases.

SURGICAL CONSIDERATIONS IN THE TREATMENT OF CHRONIC SUPPURATIVE NEPHRITIS*

D. S. FAIRCHILD, M.D.
CLINTON, IOWA

During the past twenty years a good many cases of affections of the kidneys attended with pus in the urine almost, if not quite, as a constant condition, have come under my observation. The symptoms have not usually been severe, but persistent, and have incapacitated the patient for active employment. Some of these cases have been attributed to trauma and were studied primarily on account of claims against corporations. Others were supposed to be cases of renal calculi; but exploration of the kidney demonstrated the absence of stone but the presence of a chronic suppurative, interstitial nephritis which was relieved by a decapsulation or by incision and drainage. Patients have come under my care following some infectious disease, particularly pneumonia. For instance, a few years ago a patient was referred to me, by a physician of considerable skill and ability as a diagnostician, for the removal of a tuberculous right kidney. The patient was under my care in the hospital for two weeks. It was before the days of satisfactory cystoscopic examinations. The segregator appeared to show that both kidneys were involved in a suppurative process, the left more than the right. Specimens from both kidneys contained pus in which were germs identified by thoroughly competent bacteriologists as being *Bacillus tuberculosis* and ordinary pus-forming bacteria—staphylococcus, the number of tubercle bacteria being rather small and probably accidental. The kidneys were explored; neither showed any evidence of being tuberculous. One kidney was incised and drained, the other decapsulated. The pus gradually disappeared and in two months the urine was clear and normal. The patient fully recovered her health. This patient had suffered an attack of pneumonia six months before coming under my care, had recovered so far as her lungs were concerned but her health remained impaired because of the infection of her kidneys. The marked improvement immediately following the operation and the rapid recovery left no doubt in my mind as to the beneficial effects of the surgical procedure.

The infection no doubt, in many cases, travels up from the lower urinary tract and is often probably primarily of gonorrheal origin and may assume first a pyelitis, which in a considerable proportion of cases subsides with or without medical treatment, but in a certain per cent., the infection extends beyond the pelvis and becomes a pyelonephritis which continues an indefinite time.

The nature of the disease especially referred to in this paper is a mild hematogenous infection, which does not result in destructive changes or lead to abscess formation, unless through some accession of germ activity or some serious interference with kidney drainage from obstruction of the ureter.

The effect on the kidney itself is generally not serious at least for a considerable time. The organ is hyperemic and swollen, and later a proliferation of connective tissue may be expected. Some kidneys show an uneven cortical surface as from the contraction of connective tissue, as in scar formation.

The eliminating power of the kidney is not seriously impaired except on occasions, as from exposure or when an increased burden is thrown on them. Under these circumstances a rise of temperature may be observed attended by some of the symptoms generally attributed to uremic toxemia. The urine is decreased in quantity and the amount of pus is considerably increased. These symptoms, often of a serious character, subside after ten days or two weeks and the kidneys if both are diseased, resume their former condition. The pus still persists in the urine. Provided the ureter does not become occluded, the constant drainage saves the kidney from abscess formation. In a certain percentage of cases, the infection reaches the organ through the circulation, as in post-typhoid and post-pneumonic conditions. The kidney drains through the ureter for a considerable time—a year or more perhaps. The patient's health is impaired but there are no very urgent symptoms. If, however, some process develops in the ureter whereby it becomes blocked, more or less completely, single or multiple abscesses may be expected to result. Either in consequence of this or of the kind and severity of the infection, a nephrectomy becomes necessary.

It is not uncommon for the kidney to become infected scondarily from some more remote focus. When this occurs, the embolic nature of the process is likely to determine one or more abscess formations. In such cases it is not uncommon for the abscess to drain into the pelvis of the kidney and thus be discharged intermittently with urine; although pus may be found in the urine as an almost constant condition.

If the ureter is permeable, the kidney may remain without any material change for some time and may even recover without any operative procedure. In the event of a blocking of the ureter the kidney may become practically destroyed by the advancement of the suppurative process.

I have met a considerable number of mild infections of the kidney secondary to infected wounds, as compound fractures and more or less extensive skin infections associated with wounds. I have likewise met embolic processes following the same conditions involving abscess formations which required nephrotomy and sometimes nephrectomy.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

It is not the purpose of this paper to discuss the severe infections but the mild, in many cases of which the patients recover under proper dietary regulations and rest.

I trust it will be taken for granted that I am not confusing pyelitis with a suppurative process which has invaded the connective tissue structures of the kidneys extending along the tubular system. It is admitted, however, that an ascending infection may have at first involved the pelvis, and when limited to this part of the kidney, subside without any radical treatment being employed.

Patients afflicted with these milder infections of the kidneys do not, as a rule, suffer from severe symptoms unless subject to exposure or to conditions very materially increasing the work thrown on these organs, but there is an impairment of health which ranges from a moderate indisposition to confinement to the house, as illustrated briefly by a few cases.

Case 1.—A locomotive engineer who had pus constantly in his urine and had been unable to perform any part of his duties, attempted to run his engine a hundred miles. Before completing his run, he was taken with vomiting and severe pain in the abdomen. The same night he was seized with a chill followed by a temperature of 104 F. and soon afterwards, by some uremic symptoms. The quantity of the urine was greatly reduced and loaded with pus. Elimination by the skin and bowels gradually brought about an improvement, and in two or three weeks he had regained his former condition except that the amount of pus in the urine was materially increased for two months or more. He would not submit to operative treatment and at least for five years more the condition remained unchanged.

Case 2.—A railway conductor who for a year had declined in health and was able to work only at intervals, came under my care. Pus was found in urine. The right kidney was tender to pressure and somewhat enlarged. After three months of general treatment without improvement, the patient submitted to an operation. The organ was exposed and found suppurating but no distinct abscess existed. The kidney was freely incised and allowed to drain. Pus soon disappeared from the bladder urine but was found for some time on the dressings. The wound finally closed with complete recovery.

Case 3.—Another patient had an inflammation involving the right kidney which had persisted for several months. He began to suffer from chills, which recurred every two or three weeks followed by a temperature of 102 to 104. Pus was constantly present in the urine but attending each of these attacks the quantity was very considerably increased. In five or six days the temperature would reach the normal, and the pus in the urine would very materially decrease in quantity. Finally, following one of these attacks, the secretion of urine nearly ceased and uremic delirium supervened. The kidney was exposed; abundant evidence of long-standing inflammation appeared but no pus accumulation was found. Notwithstanding this, the kidney was incised from one pole to the other. It was allowed to drain without the use of any tube or tissue in the kidney wound. All the conditions promptly improved. Pus rapidly disappeared from the bladder urine but continued on the dressings for some time.

The surgical treatment I have employed in the form of kidney lesion referred to in this paper is decapsulation or incision. It is true the operation of decapsulating the kidney has fallen into considerable disfavor, but I cannot avoid the belief that the procedure has considerable merit after all, not perhaps in some of the forms of disease for which it has been advocated from time to time; but in many of the kidneys now under consideration, it is certainly curative in its effects. It very obviously would not be a rational procedure for the purpose of drainage of infected kidneys.

I have in mind certain patients in poor health in whose urine pus had been present for a considerable time, one kidney or the other or both, being affected. Ordinary treatment having no good effect, the organ was exposed and found hyperemic and swollen; incision not seeming indicated, decapsulation was resorted to, not quite so extensively perhaps as has been recommended, but sufficiently to release tension and allow, theoretically at least, an improvement in nutrition and thereby an increased resistance to morbid processes. However this may be, I am certain of the curative effect of the undertaking. With the patients whose symptoms and whose kidneys show a more marked influence of the infection, a more radical course is necessary; the kidney should be incised and allowed to drain. No drainage material whatever has been introduced into the kidney incision unless an abscess exists. The wound in the loin has been partly closed and two or three cigarette drains extending down to the kidney.

A consideration of my own cases and many in which treatment by decapsulation was employed some years ago with much apparent success, which also unfortunately led to the extension of the operation to impossible conditions involving degenerative changes, leads me to believe that if the procedure had been confined to cases of infections of the organ, this treatment would not have fallen into discredit. It cannot be doubted that many of the large congested and sometimes mildly infected kidneys that were anchored by means of a detached flap or even by a more liberal use of the capsule, were benefitted more by releasing the tension than by the fixation itself, whereby the circulation and nutrition were improved. It may be noted in this connection that the fixation of a normal kidney which is subject to even rather wide excursions carries with it no advantage to the patient unless the mobility causes distinct pain.

I have already attempted to say that a more serious and widely extended infection not referring to abscess formation—needs incision, for only in this way can drainage be affected, but in milder types, decapsulation is generally sufficient, placing, as I believe, the kidney in a vastly better condition for recovery.

ABSTRACT OF DISCUSSION

Dr. A. H. Ferguson, Chicago: I cannot see the use of decapsulation of the kidney for chronic inflammation of that organ. There are other and better methods of treating such a kidney. In cases of extensive abscess, one can do a nephrotomy and drain. In cases of a milder nature nephrotomy is not indicated. Washing out the pelvis of the kidney, drainage of the pelvis without opening the kidney, treatment by vaccination, are methods we should resort to before undertaking capsulation. If all these fail, and the kidney is much destroyed, we must do a nephrectomy. I have seen two or three cases in which there was pus in circumscribed areas here and there in the kidney, but simple excision of the abscesses effected a cure, the kidney itself remaining untouched.

Dr. D. S. Fairchild, Clinton, Ia.: I did not intend to convey the idea that I treated suppurating kidney by decapsulation. I referred to cases of mild infection in which decapsulation might bring about a beneficial result by relieving tension and allowing an improved condition of nutrition. In all cases of suppuration of the kidney in which pus is distributed throughout the organ, the kidney ought to be excised. I think that Dr. Ferguson was much given at one time to decapsulation for various conditions, but in my paper I stated distinctly that in cases of mild infection in which we do not want to do a very radical operation decapsulation, if the capsule is tense, is indicated. In cases of severe infection excision is the only thing. Of course we do not want to remove the kidney if a good result may be obtained in any other way.

THE PROPER TREATMENT OF INTRAPERITONEAL ABSCESS IN THE LOWER ABDOMEN

WITH SPECIAL REFERENCE TO RECTAL DRAINAGE IN PELVIC ABSCESS*

ARCHIBALD MACLAREN, M.D.
ST. PAUL, MINN.

The successful treatment of any intraperitoneal accumulation of pus depends on proper drainage. In women it is a well-established fact that drainage through the vagina is at times better than draining through the anterior abdominal wall. Mr. Pollard has said that occasionally in his experience drainage through the rectum has been better even than vaginal drainage because it reaches a lower point in the peritoneal cavity. In dealing with an accumulation of pus in the peritoneum the proper method to pursue is to treat the rectovesical or recto-uterine pouch as though it were always infected, for even though it does not contain pus in the early stages of localized peritonitis, it is very likely to become infected later, as we all have seen in a great many instances. The extension of pus to near-by peritoneum, and especially to the bottom of the pouch, is not a dangerous accident if proper drainage is provided. Van Buren Knott has very pertinently put it: "Why should we be afraid of general peritonitis? To-day we know how to deal with and cure this disease"; and if we see the cases early enough and establish proper drainage at once, our general peritonitis patients will usually recover." Proper drainage when combined with the Fowler position, is the most important point in effecting a cure. Dr. Knott's experience in over 160 consecutive cases of appendiceal abscess, in every one of which he has broken up the abscess walls and removed the appendix, with but two deaths, is very convincing. His plan, which I believe to be founded on sound surgical principles, is always to drain the bottom of the rectovesical or recto-uterine pouch with a large-sized split rubber tube, carrying a wick of gauze through the anterior abdominal wall just above the symphysis. I believe that if this plan is pursued the necessity for vaginal or rectal drainage will in the future be very much reduced. The older methods of drainage of abscess cavities and removing the appendix only when it presented itself and could be reached easily have resulted in many later accumulations in the pouch.

A good plan of procedure, and one which I have followed a great many times, is first to open an accumulation of pus in the pouch either through the vagina or through the rectum, to put in a winged rubber tube and then immediately proceed to open the abdomen above and to deal with the pathologic condition according to general surgical rules. By this method the amount of pus is considerably reduced and other, often unsuspected abscesses are found and evacuated.

The purpose of this paper is to show that rectal drainage is no more dangerous to the patient than vaginal drainage, and that a very useful addition to our operative measures and occasionally a life-saver. Two years ago I presented a short paper[1] on rectal drainage to the American Surgical Association and recited the histories of five successful cases in which pelvic abscess had been opened and drained into the rectum; all of these were cases of men or boys and the drainage was used in the same manner that we have been in the habit of using vaginal drainage in women. I wish now to offer my further experience, and to speak of the few comments which have been made on this subject in the English and American medical press.

The five cases already reported were all due to perforative appendicitis, in which the abscess cavity had originally been opened through the anterior abdominal wall. These cases had progressed favorably for several days and then gradually began to do badly, showing return of fever and pelvic pain. A rectal examination several days after the primary operation demonstrated a collection of pus in the rectovesical pouch with bulging of fluid against the anterior rectal wall. Opening these abscesses through the rectum and drainage with a winged rubber tube yielded most satisfactory results. At that time I also advised overdistention of the sphincter so that there would be no back pressure from the rectum into the abscess cavity. Whether this last procedure is of any value or not I cannot say; but it has the negative virtue of doing no harm.

Belfield,[2] says, that the statement which I had made, namely, that all pelvic abscesses in men were due to perforative appendicitis, is certainly erroneous; in which he is entirely correct. Suppurations from the prostate or seminal vesicle are true pelvic abscesses and they are most apt to point in the perineum, and consequently should be opened at that point. What I should have said was that practically all intraperitoneal abscesses were due to perforation of the appendix and that abscesses in the rectovesical pouch should be opened into the rectum. The objection has been made that because the normal intra-abdominal pressure is approximately 16 pounds to the square inch, postural drainage is not needed; that ordinary drainage is all that was necessary. This is no doubt true in the majority of cases; but every surgeon knows that it is not always true; that dependent drainage with intraperitoneal pressure is much better than ordinary uphill drainage under the same condition. When the intestinal coils and omentum become adherent to each other, the intra-abdominal pressure becomes decreased, and under these circumstances a suprapubic drain only allows the escape of the overflow and the pouch is never emptied.

Mr. Archibald Cuff in the London *Lancet*, a few months ago, in speaking of the treatment of appendiceal abscess says, "One advocate of rectal drainage whose zeal would seem to be based on a slender and unsatisfactory experience, admits on one occasion opening the bladder by accident." This sounds as though the accidental opening of the bladder in this case was a very serious matter, while, as my first report states, the patient had not the slightest trouble, not even discomfort as a result, and recovered perfectly in spite of this accident, which ought not to have occurred. In this case to make sure that I had really opened the bladder I introduced my finger into the bladder so that I could feel the prostatic opening of the urethra. I made no attempt to close the opening, but proceeded to open the abscess behind the bladder. That same night the man passed bloody urine normally and did not even develop a cystitis. This accident happened before I had perfected a line of procedure to be followed in this operation, and when the rectovesical pouch was opened practically by the sense of feeling and without the operator's being able to see where it was best to make the opening.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

[1] Surg. Gynec. and Obst., June, 1908, p. 671.

[2] Belfield, W. T.: Prog. Med., December, 1908.

In a different vein is the article by Mr. Bilton Pollard,[3] surgeon to the University College Hospital. Mr. Pollard says that he was just about ready to publish an article on rectal drainage when my paper[1] appeared. He reports one case of diffuse septic peritonitis with a large intraperitoneal pelvic abscess of three weeks' duration, in which rectal drainage was the only operative procedure, with perfect recovery. Of accumulations of pus in the pelvis following an ordinary laparotomy for appendicitis, he says that he has opened several through the rectum and always with success. When I wrote my paper two years ago I had not operated in any case of pelvic abscess just like this one, but I mentioned this kind as particularly suitable, and expressed my intention of operating in the first one which presented itself.

As already mentioned, the five cases reported two years ago were cases of pelvic abscess following intraperitoneal operations for appendicitis, in which several days after the primary operation accumulations of pus in the rectovesical pouch were opened and drained by rectal section, and all of these patients recovered.

REPORTS OF CASES

Sixth Case.—One week after Dr. Pollard's report was published in England, I operated, in a precisely similar case, on a boy aged 14, sent from Canby by Dr. J. S. Kilbride. The patient was profoundly septic, the perforation having taken place ten days before. Every one was agreed that the boy was growing rapidly worse. The abscess apparently was not adherent to the anterior abdominal wall but bulged markedly in the anterior wall of the rectum. At least a pint of thick, very offensive pus was evacuated by rectal puncture and a rubber tube was put in; the next day the patient's temperature and pulse were practically normal. On the second day he was "cured." On the sixth day the tube was removed, and on the twelfth day the patient went home. He has been perfectly well ever since.

Seventh Case.—This was one of the typical non-operative cases of Ochsner in which the abscess was probably going to rupture back into the free peritoneal cavity before the eighth day. In this kind of case on several occasions I have seen the patient suddenly die on the fifth or sixth day. The patient in this case, a little girl, aged 7, was desperately sick; perforation had occurred five days before; temperature was 104; pulse 130 to 140, and of a very bad character; there was general abdominal distention; and excessive bulging through the rectum. One-half pint of pus was evacuated through the rectum. The patient did well until the fifth day after the operation. On the seventh day anterior abdominal section was made, and a large abscess about the appendix, containing gas, was opened. The patient died on the tenth day. This child should have had abdominal section either the same day as the rectal section or not later than forty-eight hours after. I believe that in this case the rectal section prolonged life, even if it did not save it.

Eighth Case.—The patient, a boy aged 7, who had been sick for ten days, was seen with Dr. Buckley of St. Paul. This was much the same kind of case as the one just preceding. Temperature was 99; pulse 120. There was decided bulging of the anterior rectal wall, which was first opened and a half of a pint of thin watery offensive pus let out. The patient was much better for two or three days; on the fifth day he was worse again. Temperature was then 101; pulse 120. There was a mass in each loin; these were opened and drained in front, and the appendix, which was a long one and ran over the brim of the pelvis, was removed. The patient then promptly recovered.

Ninth Case.—The patient, a boy, was sent by Dr. Campbell of South St. Paul. The case was one of ordinary appendiceal abscess, seen first on the seventh day. The abscess was opened above behind a gauze tampon, and one ounce of thick pus was let out. I could not distinguish the appendix or find an enterolith. After closing the wound and putting in a drain, and just before I sent the patient from the operating room, I made a rectal examination to find a separate pelvic abscess containing fully three ounces. This separate abscess, not discovered in the earlier stages of the operation, was opened into the rectum. The boy made a perfect recovery and has been well ever since.

Tenth Case.—The patient, a boy, aged 6, was sent by Dr. Boothby, Hammond, Wis.; he had suffered from perforation of the appendix eight days before. Pathologic condition was one of acute, suppurative, perforative, gangrenous appendicitis. On July 19, 1909, the appendix was removed after the abscess was opened; a drain was put through a stab just outside the wound; on the seventh day the patient was found not doing well; temperature was 101. That night the patient was uncomfortable, crying most of the time from distress in the rectum. Rectal examination showed fluid in the rectovesical pouch. On the eighth day a rectal section was made, and half a pint of clear serous pus, followed by two drams of thick pus, was evacuated, a small rubber drainage-tube was inserted in the opening in the rectum. The following day the boy felt much better; on the third day after the second operation the tube came out and was not replaced. The patient recovered, and has been perfectly well ever since.

Eleventh Case.—The patient was a young man, aged 25, suffering from a first attack which had begun five days before; he was able to work until two days previous to the operation, when he began to suffer very intense pain and was confined to his bed. Temperature was 100; pulse 90. There was general rigidity of all abdominal muscles and intense pain. Pathologic condition was one of general septic peritonitis, due to gangrenous perforative appendicitis, pelvic abscess and an accumulation of fluid in right loin. Rectal section was first made; one-half pint of turbid, very offensive serum was evacuated and a tube was put in; when the abscess was almost emptied the fluid became true pus. This was immediately followed by laparotomy and removal of appendix and a suprapubic drain was put into a stab wound over the symphysis; a gauze drain was put through the wound into the right loin. The man was put in the Fowler position. On the third day the suprapubic drain was removed; on the thirteenth day the rectal tube was removed. This patient recovered and has been well ever since.

Twelfth Case.—The patient, Mr. C. of Detroit, Minn., aged 30, was sent by Dr. Charles Greene of St. Paul. There was a mass in the right side and fluctuation in the rectum. The pathologic condition was one of acute suppurative, perforative appendicitis with abscess pointing toward the rectum. Operation was performed on the sixth day of the first attack. Rectal section was first made, and four ounces of offensive pus evacuated; a drain was put through the anus into the abscess cavity, and this was immediately followed by laparotomy. The adhesions were so dense that I could not reach the abscess cavity, even after deep dissection; the drain had to be put through stab outside of wound. This patient returned three months later and had his appendix removed.

Thirteenth Case.—C. A., patient of Dr. Rider of Shakopee, was operated on by my partner, Dr. Ritchie, in his second attack, seven days after perforation. The appendix could not be found; the abscess was opened and drained. On the ninth day after operation the patient began to have pelvic distress and a sense of pressure in rectum. Rectal section was made and a pint of very offensive pus was evacuated through the rectum and the abscess drained. Three months later the appendix was removed. The patient recovered and is now perfectly well.

Fourteenth Case.—F. A., aged 6, patient of Dr. Rudolph of Ellsworth, Wis., suffered with several mild attacks of colic lasting about half a day each. The present attack began with very severe pain and vomiting seven days before I saw the case. The pathologic conditions were acute, suppurative appendicitis; localized pelvic abscess, fluctuating through the rectum; localized collection of pus just outside of McBurney's point; eight ounces of thick offensive pus; no enteroliths. The operation consisted: first, of rectal section, which let out four ounces of thick offensive pus; a drainage-tube was then put in and this was immediately followed by laparotomy. The abscess to the outer side of the cecum was opened, and drained with two cigarette drains through stab just outside of the wound.

---

[3] Pollard, B.: Brit. Med. Jour., July 25, 1908.

One month later the patient came back with another attack of appendicitis; this time the appendix was removed; the patient promptly recovered and has been perfectly well ever since.

Fifteenth Case.—J. S., aged 20, patient of Dr. Breed, Rock Elm, Wis., had suffered previously from several attacks. The present attack commenced eight days before the patient was seen; he had suffered with constant pain in the rectum from the very first of this attack up to the present time. The pathologic condition was one of acute suppurative, perforative appendicitis. The abscess was well walled off; there was a large accumulation, fully half a pint of thin serous pus in the rectovesical pouch; and another accumulation of thick pus in the right loin. Rectal section was first made. This was followed by a cross-muscle incision in McBurney's point. The abscess in the loin was opened, which showed no apparent connection with the pelvic abscess cavity. The rectal drainage-tube was removed on the fourth day. The patient promptly recovered, and has had no further trouble.

METHOD OF PROCEDURE

The position used is the exaggerated position (Pryor), the one usually used in making examinations of the female bladder with the cystoscope. The most important part of this position is the use of straps over the shoulder, fastened to the uprights holding the feet, to prevent the shoulders from slipping away when the head of the table is dropped. I have found that a weighted vaginal speculum will expose the anterior wall of the rectum fully as well as it exposes the vault of the vagina in the similar operation for vaginal section.

One long-bladed retractor for the anterior wall is necessary to hold the bladder out of the way. The bladder having been catheterized to prevent accident (a thing I omitted to do in the case related), the rectum should be irrigated until fecal matter is removed, and then sponged out with alcohol. After the rectum has been well cleaned and the bulging anterior wall well located, the abscess should be opened with long, sharp-pointed scissors, used as a dilator. After the rectovesical or recto-uterine pouch is opened and the fluid let out the dilator should be kept in place until a quarter-inch, winged rubber tube can be passed well up into the cavity; then the sphincter should be dilated.

There are comparatively few vessels in the posterior vaginal wall, but as has been shown[4] there is some danger of hemorrhage following rectal section, more, I am sure than in vaginal section, so that I am inclined to believe that in these cases the lesser procedure of rectal puncture would be the operation of choice.

Vaginal puncture I do not like; it is too blind and does not give sufficient room for further exploration, but in these cases, all that is necessary is an opening through which to pass a drainage-tube.

It has been a great pleasure to see the relief and comfort which these patients have received from rectal drainage, and to note the rapid drop of temperature and pulse which followed this very insignificant operation.

412 Holly Avenue.

ABSTRACT OF DISCUSSION

Dr. J. M. Baldy, Philadelphia: It is exceedingly unfortunate that we should have to discuss the subjects of this paper, but as some cases—fortunately, an exceedingly limited number—makes its discussion necessary, it is fitting that we give it careful consideration. The existence of such cases, in the present state of modern surgery, is a disgrace; it implies that there is gross neglect on the part of the physician who referred the case to the surgeon primarily, and the grossest possible neglect on the part of the surgeon to whom such cases are sent, for not dealing with them properly.

In the women it is a very simple matter. No one would think of taking such steps in a woman to secure drainage. The vagina would naturally suggest itself, for more reasons than one, as the place through which to make an opening into the abscess. If the case occurred in a man, it would imply that the surgeon would first go into the abdomen, clear up the nucleus of infection, and then deal with the opening secondarily. All we would have to do in that case with the condition in the pelvis would be simply to drain for a day or two, and that would be the end of it. In men, of course, if such cases do occur they must be rare in the hands of a good surgeon. Then it may be justifiable to open the rectum. But one would question the skill of the surgeon who had done the primary operation. There ought to be such a small proportion of these cases that it should really be unnecessary for us to consider them; but if they do occur from neglect of clinicians or of immature surgeons, the thing to do is to open the rectum, secure free drainage and permanent drainage until the condition is cleared up, then close the opening, and that is all there is to be done.

Dr. Maurice H. Richardson, Boston: Long ago, in the early days of appendicitis, when everybody waited for the abscess to form, nearly every case of appendicitis was fatal. The cases came to us—cases of abscesses of this kind—and many times we observed an abscess opening into the rectum, which would perhaps break under the pressure of the finger. I also observed in many cases that if we had twenty-four hours to watch the case before the operation, the abscess would break into the intestinal canal, and the patients would recover. This is Nature's way of doing things, and it seemed rational to operate through the rectum. Years after the appendix was removed through the abdomen. It seems to me, of course, that the only cases of this kind that we see now come to us through ignorance, perhaps on the part of the patient, or—but very rarely—on the part of the physician. But some methods of treatment—for example, the treatment of walling off a local peritonitis so that it will not become general, if not done properly, or if done by one who does not understand the physical signs of abscess, will cause just that kind of a case. I have seen this happen in a few cases of pointing into the rectum in appendicitis.

I see cases of appendicitis frequently in which the pus connects with the tubes in the female, and the result is an undesirable one. As Dr. MacLaren has said, these are the cases in which the abscess will open through the rectum, and the original focus of infection can be sought for with great safety afterward. This is a distinctly advantageous method of treating these few deplorable cases which through many grave dangers have come to rectal opening.

Dr. A. MacLaren, St. Paul, Minn.: These cases occur in the hands of every man who does a great deal of this work, and while they are undesirable cases, there must be some way for taking care of them, and it is for this purpose and none other that I presented this paper.

Daily House-to-House Visitation of Non-immunes in Campaign Against Yellow Fever.—A Veracruz daily paper has recently published in full the address on this subject read at the meeting last October at Richmond of the American Public Health Association by Dr. C. M. Garcia, in charge of the work at Veracruz. In addition to the usual prophylactic measures, screening, isolation of patients, etc., the Mexican National Board of Health sends inspectors to every person known to be not an immune, whether they are residing in or merely passing through the old yellow fever zone. This is done daily regardless of whether or not the disease is epidemic. By thus keeping the non-immunes under constant medical supervision, the first onset of possible disease is recognized at once, and the authorities are able to apply isolation and disinfection from the start. The Journal described in detail, March 23, 1907, page 1048, the successful campaign against yellow fever in Mexico, commenting especially on its eradication in Veracruz which for centuries was one of the principal hotbeds of the disease.

HOW SHALL THE STOMATOLOGIST BE EDUCATED?

EUGENE S. TALBOT, M.D., D.D.S.
CHICAGO

It is a popular idea that "the dentist on graduation is better equipped for practice than the physician." This is misleading, not only to the dental graduate, but also to the physician and the laity. The statement was tenable seventy years ago when the first dental college was established and dental mechanics only were practiced, but modern research has shown us that many incipient diseases first show themselves in the mouth by their effect on the mucous membrane, alveolar process, jaws and teeth. These conditions frequently become serious.

In conversation with some of the members of the Council on Medical Education, in regard to the medical education of the dentist, they were surprised to know that further education was necessary. They were under the impression, that the graduate of dentistry had received a full and complete education; that is, all that was necessary to fit him for his special branch of medicine.

There are a few dentists who, after they have been in practice a short time, realize that they know little of the treatment of diseases of the mouth, so necessary at the present time. Some are willing and able to take a medical course to prepare themselves thoroughly to become stomatologists. Others would like to do so but circumstances will not permit it.

NO CREDIT FROM THE MEDICAL SCHOOLS

The medical school does not give credit for any part of the course of the dental graduate (and rightfully), because he has scarcely a smattering of the fundamentals of medicine. It is necessary for the dentist to take a medical course of four years, over and above the three years spent in the dental school. In the best dental schools, the Dean will tell you the dental students sit in the same room, hear the same lectures, and stand the same examinations as the medical students. All know the dental student is not required to have the close marking required of the medical. What a disgrace for the dental graduate after a three years' course in one department of a university to have so vague a knowledge of the fundamentals of medicine that he cannot get one year's credit in another department in the same university although he has been sitting on the same seat, in the same room and hearing the same teacher on the same subject. Teachers on the fundamentals of medicine have informed me many times that dental students did not need the same serious consideration of the subject as the medical students required, and therefore their examination was not so severe; hence, the dental student is allowed to slip through on a lower average than the medical student.

The dental student on graduation knows little or nothing of the fundamentals of medicine, no matter how well he may have been taught. The reason is that the dental student on matriculation, is immediately put to work on the mechanics of his profession. The entire environment and atmosphere of the school is mechanics. The contrast between the mechanic and the biologic is so great that the student immediately asks the question. "What is the advantage of all this study of anatomy, physiology, pathology, chemistry and therapeutics when the care of the teeth is all I require?" Thus the atmosphere of the school itself makes the student a mechanic rather than a broadly educated man.

THE DEGREE OF D.D.S.

Some thinkers are trying, or rather expecting to raise the standard of the D.D.S. to equal the M.D. degree, and thus to an honorable position. To my mind, it can never be accomplished. The D.D.S. will always be considered an inferior degree. To make the degree equal to the medical the student must study the same number of years. Then, why not confer the medical degree? The student will not tolerate an inferior degree. Present methods of dental teaching will not improve the student's mentality though a six-year course be required for graduation.

STOMATOLOGY AS A SPECIALTY

There can be no question that men proficient in the mechanics of dentistry (to repair and restore lost parts), and men to treat diseases of the mouth (which includes the jaws and alveolar precesses), are essential. Shall the specialty be divided and the dentist confine himself solely to the mechanics of the teeth and the stomatologist to the diseases of the mouth, or shall the student be so educated as to combine both?

If the specialty is to be divided, dental schools are wasting time and money in even attempting to teach the fundamentals of medicine. There are, in the United States, fifty-four well-equipped schools to teach the mechanics of dentistry, and they are all that can be desired in this direction. The stomatologist, on the other hand, is losing time in not acquiring a better foundation for the practice of his specialty. He should matriculate in the medical school and obtain a thorough medical education, since modern research has demonstrated that not a single disease of the mouth, jaws and teeth but has a systematic relationship. Personally, I am of the opinion that the two departments, pertaining to all operations in the mouth, cannot readily be separated. The question is then, "How Shall the Future Stomatologist be Educated?"

INTERNATIONAL ASSOCIATION OF STOMATOLOGY

In August, 1907, there was organized in Paris, France, The International Association of Stomatology. The delegates to that meeting all held medical degrees from universities and colleges in the various countries from which they came. Nearly every country was represented. The object of this organization is to urge a medical education alike in all countries for those practicing diseases of the oral cavity.

At this meeting, two questions were settled: First, That a complete medical education must be required of every dentist. Second, the word "stomatology" was defined as meaning the science that treats of diseases pertaining to the mouth; the "stomatologist" is one who treats diseases of the mouth.

THE QUESTIONS TO BE SETTLED

At the second meeting of the A.S.I., held at Budapest, August 1909, the following paper by me, "How Shall the Stomatologist be Educated?" was discussed. The thoughts therein expressed were incorporated in a report prepared for universal discussion. These questions are to be sent to members in the various countries for careful study, and are here presented for your consideration. They are as follows:

a. When is it best to begin the special studies; during the time of the general medical studies or immediately after these?

---

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

b. Advantages and disadvantages of each.

1. Special studies begun during the special medical course.

2. Special studies begun immediately after the general medical course.

c. Length of time required for special studies of each system.

d. Details of the special studies of each system.

It is necessary that these questions be seriously considered by the members of this section, since they must serve as the foundation for future dental education in many, if not all, the countries, and also for the lengthy discussion before the A.S.I. at its next meeting in Paris, 1911. It will be necessary also to publish this discussion in full in the Bulletin for 1910, Volume III, from the JOURNAL of the American Medical Association, in order that it may appear some months previous to that meeting, so that an intelligent understanding of the subject may be presented from each country.

The fathers of American medicine, the late Drs. N. S. Davis, Gross, Sayre, Flint, Toner, Pancost and many others, believed that diseases of the mouth, including oral hygiene, the most important study of the human body. Stomatologists are of the same opinion. This being the case, should not this specialty require the same method and the same length of study as the lesser specialties of medicine? The dental profession have not yet awakened to the seriousness, importance and scope of their calling.

The main point and first to be considered is, how can the stomatologist be educated and not lose time, but have all his studies count for future work. At the present time, there are two methods of studying medicine in the United States, hence the education of the stomatologist must be based on these methods, subject to more modern improvements. Both medical and dental students, at the present time, must possess a high school diploma or its equivalent; therefore, they start their chosen profession on an equal footing. In some medical schools, the high school graduate is allowed to matriculate, pursue a four years' course and graduate with an M.D. degree. The other method has been worked out by Dr. John Milton Dodson[1] as follows:

> "With the last decade there has developed a plan in several American universities under which a student takes, during the junior and senior years, those sciences which constitute the first two years of the medical curriculum. Credit for the successful completion of the work in these branches is permitted to count both toward a baccalaureate degree in the collegiate department and toward the degree of M.D. in the medical school. The student is thus able to secure the baccalaureate degree and the degree of M.D. in from six to seven years after his completion of the high school course and his matriculation in the university. The plan has extended rapidly, it being now in operation in over thirty American universities. It is believed by many educators to be the best solution yet offered of the problem of how to provide a good many students with a fairly adequate premedical training, and to induct them into the study, and later, the practice of medicine at a reasonably early age."

This method of teaching will, no doubt, become universal in this country. By either method the dental student must pursue the fundamentals of medicine in physics, zoology, chemistry, anatomy, physiology, embryology, bacteriology, pharmacology and the principles of pathology.

The first two years of medical studies should be conducted in the university proper since they are better equipped than the average medical college for this work. The stomatologist should continue the course to this point with the medical class and obtain credit. He should not come in contact with patients during the first two or three years of study. Laboratory work and the use of the microscope has given him considerable experience in finger manipulation. The finger manipulation cannot be more delicate than that required in the laboratory and dissecting room of a university or medical school. To offset this objection, if it can be considered one, it is essential that the student should be required to obtain as much of his professional education as possible before coming in contact with the commercial side of his specialty, which is so demoralizing to his future welfare by the present methods of teaching.

One strong argument put forth against a medical education for the dentist is the early requirement of finger skill which is supposed to be lost later in life, the student being too old after a medical education to acquire the skill necessary to perform operations in the mouth.

To ascertain the ages of entrance into the best schools in the country, I wrote to eight, requesting them to send me a report of the ages of matriculation for the past five years. Deans Koch, of the Northwestern University Dental School; Smith, of Harvard University Dental School; Kirk, of the University of Pennsylvania Dental School, and Hoff, of University of Michigan Dental School, responded.

WHAT THE TABLES SHOW

The reports are interesting since they show the youngest to be 16 and 17 and the oldest 44, with an average in Harvard and Northwestern of 23.29, and in the University of Pennsylvania 21.53. I have known students to matriculate in the dental school as late as 54 years of age. The ages of matriculation in all the other dental schools must range in a similar manner. The fallacy of this argument must, therefore, fall to the ground.

In the university medical schools, the average is lower than in the regular medical schools. Thus in Harvard and Johns Hopkins the average is about twenty, while in the schools not connected with universities the average is from twenty-two to twenty-four. Students leave the high school in this country usually at eighteen to twenty years of age. The same is true of the gymnasium in Germany and the institutes of France.

The reason that medical and dental students matriculate late in life in schools not departments of universities is that most of these students have started out pursuing other avocations. Not making a success in their chosen calling or having a taste for the professions they have sought new fields for livelihood. Few of these men have taken a high school course or have even passed successfully through the grammar school. Every year the people are becoming more exacting in regard to the education of students for the professions. This will necessitate the students entering the profession direct from the high school, thus reducing the age of matriculation to a minimum. Students of dentistry entering the medical school at twenty can graduate with both medical and dental degrees at twenty-six, which is early enough for any man to begin the practice of a profession.

The stomatologist, having finished his two or three years of the fundamentals of medicine, now has the choice of two methods. He can finish his full course in medicine before taking up his specialty, or he can take three months in the summer for his clinical work and finish in one or two extra years, thus cutting off one year in his special course and adding one to his medical course. In either case he has spent only six years as against the seven or eight for other specialties. This is certainly not too much to expect of a department of medicine recognized by medical practitioners as the most important specialty.

THE ELECTIVE SYSTEM

The elective system in medicine, as recommended by ex-President Eliot, of Harvard, is meeting with much favor. There is so much detail in each medical specialty that no one student can master the subjects sufficiently to enter into a general practice of all. Special teaching is necessary even after the graduate has finished his hospital training.

A full and thorough course of two or three years should be required of all students in the major branch of medicine, and a satisfactory examination should be required, after which the student should select the specialty he desires to practice and with the aid of the Dean select such other branches as will fit in with those of his specialty. His special training in the stomatologic hospital (dental clinic) can be continued in the schools, which are now so well equipped for special work. The courses in both general and special medicine should continue throughout the year, divided into four quarters. By this method, the student can better select the course best adapted to each year's curriculum.

SPECIAL DEGREES FOR SPECIAL WORK

Should the elective system eventually be adopted, then all the "ologies" would specialize after the second or third year of medical study. This would simplify matters and the stomatologist would then stand on an equal footing with the other specialists. It would not be a bad plan also to confer the special degree of D.D.S. on such students as become proficient in special work. The specialties should be pursued as they are at the present time. Having finished his medical course, his special teaching should be shortened one year at least. The details of special instruction can only be worked out in the dental hospital on those students who have acquired a medical course. The student's special instruction should continue until he has become proficient in the different departments and has come up to a given standard. In other words, merit should be recognized, whether it be six months or three years. The standard of requirement should be established by a committee consisting of one delegate from each university stomatological department, or still better, by the state board of dental examiners.

REGISTRATION OF SPECIALISTS

The state board of medical examiners should register the graduate of medicine and the particular specialty he has become proficient in. The law should require him to practice that specialty. Should he find later that he is better adapted to practice some other specialty, he should pursue studies along that line, stand another examination before the state board of medical examiners and be licensed to practice that specialty.

It is to be hoped that the Council on Medical Education and the Association of American Medical Colleges will soon consider the return of the prodigal son to the mother profession, and not only make provision for his welcome back into the household, but also provide for the other brothers (specialists) that the fatted calf may be distributed equally to all children so that they may all eat and drink of the knowledge of medicine and make merry.

103 State Street.

HOW SHALL THE STOMATOLOGIST BE EDUCATED?*

JAMES E. POWER, M.D.
PROVIDENCE, R. I.

In discussing the subject "How Shall the Stomatologist be Educated?" I am conscious of the fact that true science aims at the attainment of truth; honest criticism and honest discussion are the only factors that will or can assist in the accomplishment of her aim. I do not assume an attitude of criticism; I am simply responding to a call which I consider to be the duty of every member of that profession which has greater possibilities for the future than any of her sister professions, socalled.

That there are branches of pathology, or I might say of pathologic physiology, which have never been explored, is a fact too obvious for discussion here. It is an accepted fact that dentists and dentistry have, in the services which they have rendered, accomplished facts which are only short of marvelous. If we read the history of dentistry and reflect on the strides which have been made in the preservation of the teeth, we may indeed point with pride to a noble record. But we must be honest with ourselves, and if we are to assist in placing this profession in that place which it should rightly occupy among the other professions we cannot content ourselves with the fact that it is so much better than it was twenty or thirty years ago; we must ask ourselves, in consideration of the number of the thousands of men and women who are going into the profession of dentistry—as well as those who have been practicing it for years, and in consideration of the number of dental colleges which exist to-day. Does this profession occupy the position that it should occupy at present? We all know the answer, and unless enthusiasm or deceit replace honest judgment and honest opinion, the answer spells, No. Now we must submit to a little self-examination and determine whether or not the fault lies with us as individuals or as a profession, or whether or not we are doing the best we can with the training which we have received at our dental colleges. It is reasonable to believe that most of us are doing all we can to make our profession the greatest in the world. Then to continue to reason along logical lines, the only conclusion is that our education is confined too much to the mechanical or artistic department of our profession.

WHAT DENTISTRY COMPREHENDS

Before proceeding further, let us here understand whether we consider that dentistry comprises merely the making of artificial dentures, extracting teeth and insertion of fillings, or whether it comprehends something more; for instance, whether it has a direct relation to histology and physiology; whether it should have a part in the interpretation of physiologic and pathologic metabolism; whether it should have a complete knowledge of those factors which preserve health and breed disease, not only of the teeth, but of the mucous membranes from the mouth through the whole alimentary canal, with all its adjacent and component parts? If we accept the former definition, then I say that we are highly trained technicians, and yet not as highly trained or as well developed in the manipulative skill as are some of our colaborers, who are not considered by us to belong to a profession at all.

If we accept the latter, then I say that our education is inadequate, and that in order to fit ourselves to fulfill the obligations which are expected of us, and to make our profession all that our fathers intended it should be, we are obliged to call for a change in the teaching of the future students of dentistry. Let us agree to stop asking for recognition, from a profession which many of us believe is only to be our equal, namely, the medical profession. There never was and there never will be either an individual or a profession that need call for recognition. Recognition is that indefinable something which is always thrust on the individual when that individual occupies the position which is deserving of such recognition. The world is the judge and the world gives the recognition as soon as we deserve it. No sooner, no later.

FOUNDATIONS IN DENTISTRY AND MEDICINE

That the foundation on which the dental graduate is sent into the world is greatly inferior to the corresponding foundation of the graduate in medicine is a well-known fact to all who have taken the time and patience to investigate the educational advantages of each. The dental graduate will tell you that he studied the same subjects as did the medical student. This is true, but the question is, Did he study them as thoroughly, or rather, was the standard for him and his medical brethren equal? In a large majority of cases he is laboring under a delusion if he believes that he knows as much, or even if he thinks he was given the same advantages in learning pathology, bacteriology, biological chemistry, or even anatomy, or physiology as was his medical brother. And now let me anticipate your question. Why? Because this branch of the science is taught by the professors of medicine, and in some instances the members of the dental faculty, who were graduated twenty-five or thirty years ago, do not seem to understand the importance of a proper medical education. We are apt to become subjects, if not indeed victims, of our environment, and the dental student is no exception to the rule. He breathes an atmosphere while on the dental side of the college, which may give his mind a bias. This condition of mind is not always correct, and when the student comes under the instruction of the professors of medicine, the men who are spending their lives in fitting the candidate for dental honors (for that seems to me the most important part of their life's work), the mind of the dental student is apt to be antagonistic to their teachings. If the mind was directed by the dental educators (the men who first meet the students) along the proper channels, it would be receptive and instead of leaving these departments with a superficial, or I might say an artificial knowledge, they would have a foundation on which they could and would develop the future of our profession.

WHAT THE COURSE SHOULD COMPRISE

I am firmly convinced that a complete medical education is absolutely necessary for the proper practice of what the profession of dentistry means to me. In replying to the first question, "When is it best to begin the special studies; during the time of the general medical studies or immediately after these?" I will state that the studies of the dental specialist should be postponed until after the medical education is completed. I do not believe that there should be introduced into the medical course any of the special studies of the dentist except those which are already recognized as belonging to the department of medicine. If we introduce any of the special studies during this time we are destroying that which we are trying to accomplish, a complete medical training and the mind of the student is again diverted from the direct pathway. The special studies of the dentist should commence after his medical education is completed and should consist of certain branches of prosthetic dentistry, certain parts of crown and bridgework, the fundamental principles which govern the correction of irregularities of the teeth, and oral surgery. One year should be sufficient for the above named studies. The operative dentistry should consist of a practical teaching of filling teeth. and a theoretical teaching of the composition of the various filling materials. The prosthetic dentistry should consist of how to make artificial dentures, and a theoretical knowledge of the material, eliminating all the antiquated methods of making artificial dentures, leaving this for the dental historians. The crown and bridgework course should be carried along the same lines as the prosthetic course, viz., eliminating the antiquated methods of doing this work, as well as its history.

---

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June. 1910.

Have men in charge in these departments who can and will teach the short methods of doing this work. *Orthodontia* can be taught as it is taught now. I am confident that one year would be sufficient for the proper teaching, as well as the proper understanding of the special studies required of the dentist. I realize that some may say it is unreasonable to believe that one year is sufficient to teach that which at the present time takes three years to teach. In replying I will state that there must be a revolution in the present teaching, and with a medical education the student has already learned all the material, which is now but poorly taught in the dental courses. His mind is more highly developed, as well as his powers of interpretation, not only of pathological, but of all conditions pertaining to the practice of a specialty, and the time required for a proper understanding would, of course, be shorter.

To me it seems impossible that a person can learn pathology without a microscopic study of all diseased tissue. How can we understand bacteriology without studying micro-organisms, both in culture media and under the lens of the microscope? How can we understand the subject of immunity and apply the vaccines and sera to the diseases which come under our specialty if we do not understand thoroughly that subject which is already revolutionizing the treatment of disease? There is not in reality, and there should not be in name, dental pathology, dental materia medica, *dental neurology* and dental hygiene, and numerous other dental subjects which are really a part of the great subjects themselves and are included in them. It is agreed that a great deal of time is wasted in the attempt to teach these subjects, and the shame of it all is that they are taught imperfectly. If we eliminate these subjects and revise the teaching of the dental subjects, then we will have the same amount of time for the dental subjects as we have now, only we have a better foundation on which to base this work, which at most could be accomplished in one year

THE DAILY SCHEDULE

Saturday morning could be devoted to the orthodontia clinic and Saturday *afternoon to* the oral surgery, this branch including the extraction of teeth; Monday morning to be devoted to the crown and bridgework clinic; every other morning to be devoted to the practical prosthetic work, and every afternoon, Saturday excepted, to the teaching of practical operative dentistry (filling of teeth, etc.). The treatment of the orthodontia patients subsequent to the visit at the clinic Saturday morning could *be carried on during the latter part of the afternoon of the* operating days, because it requires in the vast majority of cases, but a few minutes work. The lecture on operative dentistry, crown and bridgework, prosthetic dentistry, and orthodontia could be given at the first morning exercise, which could be easily arranged at 8:30. Commence the practical work at 9:30 and continue it till 1 o'clock. Resume the afternoon studies at 2 and continue till 6 o'clock.

CONCLUSIONS

Let us make up our minds to have more *of the real*, and less of the make-believe. Let us agree on the position we are assuming. If we are highly trained technicians, then reduce the hours of study by eliminating the *make-believe* part of our course. If we are highly trained scientific physicians of special diseases, then let us *substitute the* make-believe for the real; let us pursue *the same course* as do other specialists. Why hesitate to add our names to the honor roll, to follow the footsteps of the men who have already spent more time than I have outlined to get that medical education which seems an essential equipment for us to explore those regions which are now darkened by ignorance. The value of the medical education is already proved by the fact that most of the truly scientific discoveries are made by the men *and women who have supplemented* their dental knowledge with a medical education.

In conclusion let me add those words of Hunter which inspired Jenner to make one of the greatest discoveries in modern medicine, namely, vaccination: "Don't think; but try; be patient; be accurate."

HOW SHALL THE STOMATOLOGIST BE EDUCATED?*

M. H. CRYER, M.D., D.D.S.
Professor of Oral Surgery, University of Pennsylvania
PHILADELPHIA

The question of medical education for the dentist has been under discussion for many years, and it will probably continue to be a subject of discussion for many years to come. At the first meeting of the International Association of Stomatology, held in Paris, August, 1907, that body settled to its own satisfaction these two points, first, that a complete medical education must be required of every dentist; second, that the word stomatology was defined as meaning diseases pertaining to the mouth. A stomatologist is one who treats diseases of the mouth. In consideration of these two settled principles, the following series of questions was formulated and discussion requested:

(a) "When is it best to begin the special studies; during the time of the general medical studies or immediately after these?"

---

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

(b) "Advantage and disadvantage of each."
  (1) "Special studies begun during the general medical course."
  (2) "Special studies begun immediately after the general medical Course."
(c) "Length of time required for special studies of each system."
(d) "Details of special studies of each system."

As the words dentist and stomatologist, whether intentionally or not, are accepted in the statements as meaning the same, they will be used synonymously by the writer.

If the first settled statement be correct, that "A complete medical education must be required of every dentist," it demands that, in order to become a practitioner of dentistry or stomatology, a man must have a partial or full college education, depending on the medical school he enters, must attend a four year medical course, and according to some authorities he must serve as intern in some good general hospital for one and a half to two and a half years. This constitutes a "complete medical education" according to our leading medical authorities. It is very doubtful if such an education should be required of a dentist. But suppose only the four year course in a medical school be demanded; then the student in this country will have to spend three additional years in a dental school, unless he be allowed one year for his medical education. The best dental schools are advocating four years for the dental education; if this should take place then the student would have another year before he would be allowed to take his examination for a license to practice dentistry. According to this ruling a student must devote six or seven years to his professional studies after he leaves college to qualify for practice. By combining or overlapping the work of the two courses, the time spent can be reduced to six and occasionally five years when the two schools of medicine and dentistry are in the same university.

BEGINNING SPECIAL STUDIES

With these remarks the writer will endeavor to answer (a) and will assume that the two schools belong to the same university. If a student wishes to obtain the two degrees in less than seven years, he so announces it to the deans of both schools and arrangements are made accordingly. At the institution with which I am connected, for the past fifteen years the majority of students combining the two courses have entered both dental and medical schools, and the first year have had the same instruction as those studying medicine alone, viz, the fundamental branches of medical science such as chemistry, anatomy, physiology and pathology, together with some dental technics. In the second year a similar plan is followed, with an increase of dental work, and if a student has the ability he can complete the first two years of both courses, though he will not be up to the highest standard of those taking single courses in either school. The third year is devoted exclusively to completing his dental course, and he receives the degree D.D.S. at the end of it.

(b) Observe now what happens. It is an important point in the discussion, constituting a great objection to a complete medical training, under the present conditions, for a dentist.

(1) The last two years of the student's time are spent entirely in the medical school and are occupied chiefly in clinical work. He has not time for anything outside of this. He is thus drawn away from dentistry for at least two years. Not only does he suffer from failure to keep up with new dental methods, but his attention is riveted on the wide field of general medicine. All his surroundings are medical. Even in leisure and social hours he is surrounded by medical associates, joins medical societies, etc. By the time he graduates he finds his classmates taking intern service in leading hospitals, and he naturally desires to do the same. The student drops his dentistry with his D.D.S. and becomes a medical man. Case after case can be cited in which this has happened and but few can be mentioned during the last ten years in which a student who has obtained his dental and medical degrees in the institution spoken of, has practiced dentistry or has made a specialty of oral surgery.

Thirty-six years ago the M.D. and the D.D.S. degrees could be obtained from our leading schools in two years and a half. As the course of instruction in the medical and dental schools lengthened, naturally it required longer time to obtain each degree. Fifteen years ago, and even later, a graduate in dentistry from a reputable school was allowed one year on his medical course. But times have changed; a dental graduate to-day must spend four years in the medical school even if he be a graduate of the same institution, provided he has not combined his studies and taken his work as before mentioned, with that previous understanding.

With this experience, I cannot advocate the plan of taking up dentistry first and finishing with medicine, or of combining the two full courses in any way.

AFTER MEDICAL COURSE

(2) The second question to be considered is "Shall the student begin immediately after the general medical course?" If a student has a college education and has taken a four-year-course in a first-class medical school, it is doubtful if he can afford the time or will have the inclination to spend two or three years in a dental school, as his M.D. will allow him to practice any specialty of medicine which includes the diseases of the mouth. However, from experience, the writer does not believe that this finished (?) product would be best equipped to undertake the work of the stomatologist.

(c) Length of time required for special studies of each system. It is difficult to answer these questions which are based on the assumption that "A complete medical education must be required of every dentist," as I am not in favor of this plan as settled by the A. S. I.

In my opinion it is almost useless to discuss this subject unless we can get the cooperation of medical and dental schools. The medical schools of this country have settled, for the present, on certain definite rules by which they give a complete medical education, and are not likely to change their methods for the few dental students who wish a complete medical education. With the exception of the fundamental branches of chemistry, anatomy, physiology, pathology and bacteriology the teaching of the two schools is quite different, and cannot be given by the same teachers.

SUBJECTS MUST BE SEPARATED

In many conversations with teachers of medicine and dentistry, I find it generally considered that a student should not undertake these studies jointly. If he is to study medicine he must do so with all his faculties concentrated in that direction. If he is to study dentistry his mind during his study hours must be occupied solely with dentistry; otherwise he will be second to other students who devote their full time to one object.

If a man wishes to become a specialist in any branch of medicine, whether it be surgery, gynecology or ophthalmology, it is admitted by all medical teachers that that student must take the general course of instruction first. Then after graduation if he decides to become a specialist he can take special work in the branch he selects. In other words, he must be a doctor first. Now, if stomatology is to become a branch of medicine and require the M.D. degree, the student under existing conditions should enter the best medical college possible and take its full teaching. After graduation if he has not nged his mind, he must take up the special work of ntal profession, which will require at least two nd for most students it should be three; for there is very large amount of special work connected with dentistry or stomatology.

The plan of the A. S. I., proposing complete medical education of the stomatologist, can only be carried out by leaving the mechanical work of the dentist to persons trained especially for this work. For stomatology to become a specialty of medicine it would have to be given a place in the regular curriculum of medical schools as all the other recognized specialists are, instead of being left to a separate school of dentistry as at the present time; this would mean a complete revolution in dentistry. The training of the stomatologist would extend his field so much that he would be unable to give time to prosthetic or operative work. He would have full charge of medical and surgical cases affecting the mouth and jaws; not only diseases of the teeth and mouth itself, but constitutional diseases having manifestations in the mouth, such as syphilis and gout, also deformities such as harelip and cleft-palate, malignant growths of the jaws and tongue, injuries of the jaws, diseases of the maxillary sinus and associated pneumatic spaces.

Such work as the filling of teeth and dental prosthesis and the making of regulating appliances would be turned over under the stomatologist's direction, or subject to his prescription, *to a man* specially trained for each division of this work. His *relation* to this mechanical associate *would be analogous to that of the* oculist to the optician, *the orthopedic surgeon to the maker of braces, the general practitioner to the druggist.*

This idea *is being carried out* even at the present time
to a certain extent *by leading* dentists proportionately
as they extend their own fields. Many men have their
extraction, prosthetic and regulating work, etc., done by
associates under *their direction*, although in most cases
the *stomatologist* still attends to the filling of teeth;
but even this *would be dropped* if the idea of stomatol-
ogy as *a specialty of medicine* were carried out com-
pletely.

SUMMARY

My views summed up are as follows:

The primary object in the study of stomatology *or*
any other *profession* is not the obtaining of this or that
degree, but of gaining that special knowledge which will
best *equip* the student for the practice of his profession.
To illustrate this point, many examples may be cited of
men of high standard in the dental profession who have
the M.D. degree, and also those who have not. Both
have done and are doing great work for the advancement
of dentistry, not because they have this or that degree,
but because they have knowledge and the ability to im-
part it to others and to use it in practice for the good
of humanity. [illegible] s [illegible] rese [illegible] esigned to
The *full* [illegible] medi-
educate st[illegible]

cine. It is impossible to give the student more than a speaking acquaintance with the specialties.

To properly train a student for the practice of stomatology, a special curriculum should be devised consisting of the essential features of both the medical and dental curricula, with the non-essential subjects of both eliminated.

a. To begin with, the student must have a good general education and should have considerable mechanical inclination. If he has not the latter he will never make a dentist or stomatologist.

b. A period of at least two years should be devoted to the fundamental branches of stomatology comprising chemistry, anatomy, physiology and bacteriology essentially the same as the first two years of a medical course, and in addition, instruction in dental technics and other matters leading to the next period.

c. A period of at least two years devoted entirely to the study of the mouth including all branches of clinical dentistry and oral surgery. The latter would comprise all diseases relating to the teeth, jaws and associated parts. In this course there would be besides the lectures on oral surgery, ward classes and clinics in a general hospital. At the end of his time the student would receive a degree denominating qualifications to practice stomatology.

d. If the student desires to become an oral surgeon he should then have at least one year as resident stomatologist in a large general hospital, affording practical experience not only in operative and prosthetic dentistry, but also in treatment in diseases of the mouth and jaws, such as tumors, necrosis caused by syphilis, phosphorus and tuberculosis, cleft palate and hairlip, fractures, diseases of the maxillary sinuses and associated pneumatic spaces.

With such a course as has been outlined the graduate in stomatology would be fully qualified to practice his specialty and would have sufficient knowledge of the fundamental principles of medicine to recognize and discuss intelligently with medical men the relation of diseases of the oral cavity to general pathological con-[illegible]. This plan as regards oral surgical work has been carried out to a large [illegible] the past nine years by the combined dental schools of Philadelphia in connection with the Philadelphia General Hospital. This hospital has an oral surgical staff consisting of visiting surgeons from the various dental schools and two graduates in dentistry as internes. A clinic is given once a week by a visiting member of the staff, cases of interest to stomatologists are shown and operations on the face and jaws are performed. The clinic is open to graduates and students of medicine and dentistry, many of whom come from all parts of the world, and has the largest attendance of any clinic in Philadelphia. The internes serve from twelve to eighteen months each and have full charge of all cases in which the face, mouth and jaws are involved. They gain experience not only in their specialty, but by coming daily in contact with medical men and studying general pathologic conditions, their views are broadened and they become ideal members of the profession of stomatology.

1623 Walnut Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. TALBOT, POWER AND CRYER

Dr. J. N. Farrar, New York: A complete medical college course of instruction is necessary to success in any branch of medicine. The time needed for such education is the incubating period preparatory to any specialty. No specialty should be attempted without a complete course of medical instruction. Especially is this true in stomatology, if the deeper physiologic lines of the science and art of highest orthodontia are to be well understood.

Dr. Arthur R. Dray, Philadelphia: There was a time when the medical man was required to gather herbs, etc., and to make his own medicines. To-day, with few exceptions, he has neither time nor qualification to do the work of the pharmacist and druggist. So also to-day we find the dentist, compelled by the many calls on his time, to give much of his work to the mechanic. To-morrow the dentist will cease altogether to splash about with plaster of Paris and flasks, to burn his fingers pouring zinc dies or to smash his thumbs swaging gold plates in an effort to satisfy the patients' needs. The strictly mechanical man, not needing any medical knowledge whatever, will satisfy all these wants, leaving the dentist free to treat diseases and conditions. What does this mean? Why, that the dental student of to-day who spends three or five hours out of every ten in the laboratory, could put this time at the disposal of medical studies and operative work. In the best dental colleges of the United States to-day ten to fifteen hours or more a week of the schedule periods of the student's roster are spent in the mechanical laboratory learning a trade—a trade that could be better followed by a man devoting his whole time to it, who never need see a patient or operating chair. If in the medical curriculum of any reputable medical college the strictly dental specialties are inserted in place of the strictly medical specialties we have a good working idea of the studies which the dental student would have to take to qualify himself as a dental specialist of medicine. By strictly medical subjects I mean such subjects as orthopedics, gynecology, ophthalmology, obstetrics, mental diseases, medical jurisprudence, pediatrics, etc. The dental subjects should be taught in conjunction with the medical course, being focused on with special effort as the final years are reached.

Four years is not too long a period to spend in preparation for a lifelong work. Five or more years would be a better term. By suggesting the curtailment of the time spent on the strictly medical subjects I do not for one moment wish to imply that they should be altogether slighted, for my belief is and always will be that dentistry is a specialty of medicine and should not be followed until a medical qualification has been received. Let our dental schools of to-day give a special course if they wish, granting a special license and a special degree in mechanical dentistry, this course confining itself entirely to mechanics, lasting but two years; but let them not make an effort to work against impossibilities by teaching medicine and mechanics to the same student in less time than it takes to get a medical degree.

Dr. Eugene H. Smith, Boston, Dean of Harvard University Dental School: To my mind there are but two practical methods of educating young men for dentistry. One method is so to shape their education from the beginning that it will lead directly to the specialty of dentistry; the other is first to give them a general medical education leading to the degree in medicine, and to follow this with two years of special training. In either case the preliminary training should not be less than that obtained in a four years' graded high school, which fits students to pass the entrance requirements to our leading colleges.

By the first method, if we are training students for a dental degree alone, the first year should be devoted to the fundamentals of medicine, namely: histology, physiology, bacteriology, and physiologic and dental chemistry. General chemistry should be required for entrance. The first-year medical studies should be planned to give special and advanced training on subjects that especially concern the dentist. The second and third years should be spent in a dental hospital. The clinical work should be carried on in conjunction with lectures, and the students should be taught to make application of the medical work of their first year to the cases they treat in the hospital. I think it a mistake for a dental student to have training in special dental work during his first year of study.

The second method of training a student in dentistry is to enter him as a regular student in a first-class medical school and have him obtain the M.D. degree, after which he should enter on a two years' course in a dental school leading to a dental degree.

Modern dentistry has become so extensive a profession in itself, and modern medicine so vastly different from the medicine of a few years ago, that it is a serious question in my mind whether a student can be properly educated in medicine and in dentistry in less than six full years. If I could be sure that the combined medical and dental training that I have outlined would produce skilled men as well as scientific men I should be strongly in favor of such training. I think, however, that there should be two degrees indicating this training, rather than to have dentistry practiced under the one degree of medicine. We must never lose sight of the fact that in a specialty in which so much technical skill is required it will always be necessary so to shape our courses as to produce skilled practitioners, even though we may do it at an expense of scientific men, using the term "scientific" in its broad sense.

Dr. M. H. Fletcher, Cincinnati: I am in thorough accord with the idea that many dentists, if not all, should have a complete medical education in addition to their mechanical training, since it fits one most satisfactorily for the practice of stomatology. In fact, I do not see how one can be fitted for the practice of stomatology without a full medical education, any more than one can be prepared as an oculist or throat and nose specialist without medical training. No dental college of which I have any knowledge so fits a student, since the dental courses in anatomy, physiology and pathology are decidedely inadequate. The average dental operation can be well performed without much knowledge of the laws of health and disease of the tissues, but the successful treatment of diseased tissues in the mouth and their systemic effects requires a knowledge such as can be attained only by taking a complete course in medicine and surgery.

My own judgment is that we should have stomatologists and dentists; let the dentists stop where they do now, but a student in stomatology should first take his work in the mechanics of dentistry and follow this by special medical work, the two overlapping in the middle of the course, for instance the mechanical overlapping the medical in the later part of the second year or the beginning of the third, ending the course with the medical work in the fourth or fifth year according to the length of the course. In a five-year course (which I think is short enough) the first two years should be devoted to dentistry, the medical studies beginning in the third year while the dental work is being finished. The last two years should be devoted to a medical course and hospital work such as is now required of medical graduates in the average American medical college with clinics and practice in higher dentistry, oral surgery and treatment of the diseases of the mouth.

The difficulty about the practical working of this or any plan requiring dentists to take a full medical course is that, if one spends the time and energy to take a medical course, he is almost sure to practice medicine and not dentistry nor stomatology, for the reason that the returns in medicine, both intellectual and financial, are greater than they are in dentistry or stomatology.

To be a perfectly fitted stomatologist requires greater versatility and training than does either dentistry or medicine alone, for a stomatologist must be first a skilled mechanic and artist, then a well-posted physician and surgeon. I believe that neither the fees nor the breadth of the scope in this specialty are great enough to attract many to it who have the capacity to do both well, and I imagine that for some time in the future, as in the past, we shall have many dentists and very few stomatologists. I believe that there should be a special degree conferred in certain colleges to distinguish a stomatologist from the average dentist.

Dr. Stewart L. McCurdy, Pittsburg, Pa.: As a practitioner of general surgery as well as surgical stomatology, I have observed first, the lack of knowledge on the part of the dentist of the general medical branches, and second, the lack of knowledge on the part of the medical practitioner of oral diseases.

The remedy, it appears to me, would be plain, i. e., more medicine for the stomatologist (dentist) and at least some oral pathology and surgery for the medical student. The physician knows practically nothing of the pathology of the mouth. That the future will have in store for students a four-year course for dentists and a five-year course for medicine is a probability. When this does occur the method of instruction will, no doubt, be for students in both medicine and dentistry, to take the same course for two years. This will leave two years for the stomatologist to complete his course and three years for the student who desires to specialize in medicine to complete his course.

Dr. J. P. Gray, Nashville, Tenn., Secretary of the Department of Dentistry, Vanderbilt University: I am not quite sure that I could recommend a full medical course for dental students. I fear that the length of time would prevent a student from first taking a medical course and a dental, and that the majority of students applying for a dental course would not go further after taking the medical. Most men would not have the means to do this extra amount of work. I would require the dental student to take the first two years of the fundamental branches of medicine with the medical students, being required to do all the laboratory work required of the medical student; then I think it would be better—if it could be so arranged with the medical schools—to eliminate some parts of the medical course, and in addition to substitute some studies of the dental course. Some of the work in the dental schools might be eliminated, but most of it should be given in connection with the medical course. There is no reason why gynecology, obstetrics and other medical branches could not be taken out of the medical course for the dental student and yet a degree be given commensurate with the work done by the latter. The dental branches require considerable amount of technic—more than is required in ophthalmology and otology—and a student should have some of this technic in his junior and senior years. By the elimination of the extra branches in medicine and the addition of the dental it seems that a sufficient amount of technic and dental instruction could be imparted, and a student would still have a course equal to that of some other branches of medicine. If we are to give a purely medical course, I should make the students take up the study of the fundamental branches the first two years with the medical students; then I should give the dental course with a few of the medical studies, leaving the technic for the third and fourth year of the school, and add one year more to the completion, making five years.

I have not found in my experience of twenty years as a teacher that medical men coming to us—and we have had quite a number—make first-class operators. It may be that we have received those who have been failures in medicine. I can recall but one man who made a good student and who really was highly benefited by having studied medicine. I think that the medical schools are making a mistake in not allowing some credit to students who have attended dental schools. I know the courses given here in the fundamental branches, such as anatomy, physiology, histology, pathology, materia medica and therapeutics, should give a man at least one year off, if not one and one-half years in the medical school. If they were not satisfied with them after an examination, they might then dismiss the student. The medical colleges could find out the dental schools worthy of recognition. I do not think the course in some dental schools worthy of recognition by the medical schools.

Dr. N. P. Colwell, Chicago, Secretary of the Council on Medical Education: No man should pose as a specialist in the treatment of any class of human ailments, whether diseases of the eye, of the stomach, of the nervous system, or of the mouth, unless he has first had a full medical training. Whether every dentist should first have a complete medical training or not is a question which may need considerable discussion. It may certainly be said, however, that there should be some way to distinguish between the dentist who has had a complete medical training and the one who has not. Certain it is that the former is in position to recognize more clearly causes of certain diseases of the teeth and gums than the latter, and, therefore, is enabled to treat such conditions more intelligently.

Suppose, therefore, that all dentists shall first have a complete medical course, followed by the course in dentistry. This would mean, first, that all dentists would have a better preliminary education which would include a training in physics, chemistry and biology; second, they would have more thorough courses in the fundamental medical sciences of anatomy, physiology and the like, which are now only briefly touched on in the usual course in dentistry; third, they would all have a knowledge of the etiology, symptoms, prognosis and treatment of the more common diseases not now possessed by most dentists; fourth, it would mean a higher order of intelligence of those who are to practice dentistry, and last but not least, it would mean more intelligent treatment of patients, more permanent fillings in tooth cavities, more prompt treatment of many diseases of the gums and the prevention of many such diseases and of their sequelæ, such as diseases of the antrum of Highmore, of the frontal and accessory sinuses and the like. Furthermore, if all dentists were so educated there would doubtless be a more effective movement to educate the public to more proper care for the teeth.

The chief objection would be the more prolonged course of study required, but if the dental profession, like medicine, is already overcrowded, then the future should possibly develop fewer but better dentists even as in medicine the demand is for fewer but better doctors, or, as President Faunce puts it, "fewer doctors but more doctor." After the completion of the four-year medical course it would not require an additional three years to complete the course in dentistry, since many of the subjects would already have been completed in the medical course and much more thoroughly studied than in the usual course of dentistry. Anatomy, physiology, chemistry, pathology and possibly over half of the dental course would have been completed. The time for the two courses might be further shortened by allowing the election of certain special courses in dental anatomy, dental physiology, dental pathology, dental surgery and the like, thereby leaving for a fifth year the strictly dental subjects and for clinical courses in the special study of diseases of the mouth. Since many systemic diseases have some of their first symptoms appear in the mouth which would be discovered by the routine examination of the gums and teeth, it is very important that the subject broached in Dr. Talbot's very able paper be given the most careful consideration.

Dr. Arthur D. Bevan, Chicago, Chairman of the Council on Medical Education: The problem of the stomatologist's education is certainly a difficult one to solve. It seemed to me that if five years could be devoted to the study of dentistry, the student might put in the first two years in the scientific laboratory branches with the regular medical student, and that he might take one year in general clinical medicine and surgery and two years limited to oral surgery and dentistry. With such a training, I should think that he should receive the same sort of a degree and be recognized as a doctor of medicine limiting his work to stomatology and with just as much right as the men who are limiting their work to diseases of the eye, ear, nose or throat. It would seem to me that such a course would give him a broad training for his work.

Dr. John M. Dodson, Chicago, Dean of the Medical Courses, University of Chicago: True stomatology bears the same relation to general medicine and surgery that is borne by ophthalmology, laryngology, gynecology or any of the specialties which have to do with particular organs, or portions of the body. Doubtless dentistry, in its present narrow or restricted form as a mechanical art, has grown up independently of medicine because the purely mechanical side of that vocation—the filling of teeth, the manufacture of artificial substitutes for the teeth, etc.—occupies so large a part of the time of the dental practice.

It seems clear to me, however, that the disease of the mouth and teeth are so intimately related to pathologic states in other portions of the body that they can be intelligently and successfully treated only by one who has been thoroughly educated in medicine. I believe, therefore, that the stomatologist of the future will be, first, a well-educated man, who has secured as the very minimum of preparation for his professional study, the equivalent of four years in high school, plus two years in a literary or scientific college; and, second, an educated physician, which means, at the present time, four years of training in a well-equipped medical school, this to be supplemented by at least a year of training, as an intern, in a general hospital or its equivalent in general practice outside a hospital and, third, a specialist, qualified in the treatment of diseases of the mouth and teeth by at least two sessions (eighteen months) of attendance and training in the dental department of a university. A similar course of training for the other special branches of medicine is now provided in at least one of the university medical schools.

Possibly the individual then adequately prepared for the practice of stomatology will find it of advantage to relegate a considerable portion of the purely mechanical part of his practice, *e. g.*, the manufacture of artificial dentures, of crown and bridges, of gold and porcelain inlays, to artisans who will devote themselves wholly to such work. It is idle to contend that because the fundamental medical sciences (anatomy, physiology, etc.) are included in the curriculum of the dental school, the dental student receives an education in these branches at all comparable to that acquired by the medical student. The medical school was forced to abandon the practice of granting to the dental graduate, advanced standing in these subjects because his preparation in them was found to be wholly inadequate for the intelligent study of clinical medicine. When dentistry or stomatology comes to be generally taught in a thorough and effective manner, then and then only will it be entitled to rank among the recognized special branches of scientific medicine. There are to-day a number of stomatologists of this type—men who are graduates in medicine as well as in dentistry.

DR. FREDERICK B. NOYES, Chicago: The development of the last ten years has divided medical education into two periods of two years each, the first devoted to the study of the medical sciences, the last to the application of them to the practice of medicine. The stomatologist requires the same training in the medical sciences, but the second period should be given to their application in the treatment of diseases of the mouth. That this will be about the line of progress in the future seems certain to me. It is absurd to suppose that the stomatologist should have the same training in gynecology, obstetrics, amputations, abdominal surgery, or histology, pathology, materia medica, etc., as the medical men.

After fifteen years of teaching in the dental schools, I feel that the greatest fault to be found, at least with the better schools, is the quality of the elementary work, and that this spoils the quality of all the professional studies. This condition is not confined to the theoretical or scientific subjects, but is true also of the technical and mechanical departments. There has been too much crowding for the accomplishment of a large amount of dummy dental operations requiring the construction of a specimen of every new type of bridge or denture, and especially every pet device of the instructor and too little attention to the acquirement of skill. Judged from the standpoint of the fine mechanic, the average dentist is not skilful. There has been too much tendency to despise the mechanical side of dentistry. I believe that at the present time the dental schools fail to make a reasonable percentage of their graduates mechanically skilful, and that those who excel in skill do so because of a training acquired outside of the dental schools.

It seems very desirable that the stomatologist's course should be so planned that it could be begun immediately after high-school graduation, but so as to induce as many men as possible to take more collegiate work before beginning their professional studies. This would be accomplished if two years of collegiate work before the first two years of professional work would give the B.A. or the B.S. degree. But students entering professional work direct would receive only the professional degree. The decision between stomatology and medicine should be made at the beginning of the professional work, or, in the former course general mechanical training should be given, with the fundamental medical science. This should be in the form of applied mechanics of the finest order and designed for the acquirement of skill in the handling of tools. In the last two years the technical training should be in the application of the skill acquired to the performance of dental operations and the pursuit of the medical sciences into the field of stomatology. Finally let me repeat that at the present time failure to do thorough work in the elementary subject, both scientific and practical, is the greatest fault. Three years is too short a time to do what is undertaken in the dental school and, more important than this, dental students are not required to work as hard as students in other departments of the university. The work is arranged for the poorest students. The best students find it is easy to do what is required and have not sufficient incentive to do any more.

DR. GEORGE V. I. BROWN, Milwaukee, Wis., Professor of Oral Surgery and Oral Pathology in the State University of Iowa: The ideal medical course, one comprehending premedical education leading to a degree in arts or science, then four years of medicine, at least a year of hospital service, and then approximately two years of post-graduate preparation for special or other practice, and at best a few additional years before an independent practice can be acquired, is no longer ideal when one stops to realize the hardships it entails on the less fortunate though often worthy students and the crippling of the best usefulness of many other individuals by destroying the first enthusiasm of youth and postponing the day when they can seek independence, in this day of intensely active business and professional pressure, until they have arrived at a mature age, when such knowledge comes slowly, or at the expense of much hardship if at all.

All this does not imply that these courses should be shortened, for on the contrary they are essentially necessary, but it does mean that there must be reconstruction of the educational system from the primary school up, in order that more advanced or at least better selected work may be done before entrance to college. The gymnasium in Europe accomplishes this. Why not our high schools?

The first year's course as now arranged for dental students in university and the best other schools requires attendance on nearly all of the same classes as the medical students, and in addition thereto a considerable number of hours of special laboratory work. The result is, that students of dentistry cannot as a rule do the thorough work required of students of medicine, and to this extent at least, the educational result is defective; therefore these students are not entitled to full medical credit for this portion of the work. Slight rearrangement of the curriculum by having one freshman branch carried forward to the sophomore year and an equivalent reduction in the number of laboratory hours for operative or prosthetic technics, would enable them to fully qualify in all medical branches taken at this time and yet have the advantage of early manual training. Continuance of this system from year to year would create practically no confusion and in the fourth year which as now arranged in medical colleges is largely devoted to clinical work, the branches carried forward could be completed and dental operatory work begun. An additional year of clinical, surgical, medical and dental operatory work would in five years give better preparation than could be accomplished even in six years if either medicine or dentistry alone were completed and the other taken as a post-graduate course.

The plan of work outlined could, if desired, be inaugurated at the beginning of any term in any high-grade medical college without serious disturbance of courses as now arranged, and is sufficiently elastic to keep pace with any changes in the curriculum that advancing conditions might make necessary without creating disharmony in the schools directly interested.

DR. FRED C. ZAPFFE, Chicago, Secretary of the Association of American Medical Colleges: I have the highest regard for dentistry, and I would not for a moment have it thought that I disparage the tremendous advances that have been made in that specialty. But dentistry has arrived at the parting of the ways. It must establish itself either as a profession or a trade, an art or a science. It has always seemed to me that dentistry, to be regarded as a profession, should ally itself with the professions. As it is to-day, dentistry is neither a profession nor a trade. It is practicaly in the same class as optometry. Dentistry has extended beyond its original scope—the treatment of diseases of the teeth; it now comprises the treatment of all the diseases, injuries and malformations of the mouth. It is really on a par with ophthalmology, otology, laryngology, etc. And yet, the ophthalmologist, before he can be regarded as proficient in his specialty, must have a medical foundation and from three to five years of special study. Medical educators are keenly alive to the necessity of devoting more time in the college course to general medical education, and less to the so-called specialties in medicine. The specialists insist on thorough preparation in the fundamental and subsequent study in the chosen specialty, because a thorough knowledge of the fundamentals in medicine is a prerequisite to competent and efficient specialization. But note that there must be the preliminary training in the fundamentals. At least half of the course in dentistry to-day is given over to the study of fundamentals, which are the same as those in medicine. Dentistry must properly be regarded as a part of medicine. It is based on a proper comprehension and understanding of the causes and the development of diseases of the mouth and teeth. It is no longer merely a matter of knowing how to prepare a cavity and to fill it with suitable material, or of knowing how to construct an artificial denture. That is the mechanics of dentistry and is on a par with the work of the optician.

The dentist must know why the diseased condition is present; what it means, and how it can best be treated. He must have more than finger training; he must know pathology. To know pathology, he must know anatomy, physiology and chemistry.

He can get such training in the medical school better than anywhere else. Why not, then, elevate the practice of dentistry to the distinctly professional plane? Why not establish it as representing special study? Why not make the dentist in every way a better man professionally and educationally than he is to-day? Let him get his special training after he is well grounded in the fundamentals. The specialty of dentistry will then occupy the same plane as ophthalmology and the dentist will be a graduate in medicine, with special training in the treatment of diseases of the mouth—in other words, a stomatologist.

Just how much special training he should have the stomatologist must determine. Schools of stomatology and stomatologic societies will take care of that. An education in stomatology will not be any more costly than an education in dentistry, and the graduate from such a course will be better equipped, better prepared to practice his specialty and regarded as a professional man and not as a dentist.

Dr. H. A. Potts, Chicago: At the meeting of the National Association of Stomatology, held in Paris, in 1907, it was settled that a complete medical education must be required of every dentist. Granting this, the problem of securing it confronts us.

The dental school which requires a medical degree for entrance will go begging for students, and many who do enter will be those who have made a failure in medicine. On the other hand, the best-equipped dentist will be the one who, after receiving his dental degree, continues his medical studies, finally receiving his medical degree, followed by an internship in the free dental dispensary, much the same as is now required by some medical schools.

One solution of the problem would be, first, to have the dental colleges and medical colleges under university control, with the same requirements for admission to each; second, with the dental college and medical college, belonging to the same university, be situated near each other; third, that the departments of dental histology, dental physiology and dental pathology be established in the medical school; fourth, that the medical students and dental students take the same courses for the first two years; fifth, that the dental students then pursue their clinical dentistry and the medical students pursue their study to completion.

Thus the medical student will have gained more knowledge of dental conditions as they are related to medicine, and the dental student will have acquired some knowledge of medicine, which is sadly lacking under the present régime.

The dental student, and many a graduate as well, looks on a patient with some pathologic condition of the mouth as being "in his line" or "out of his line" of treatment. When he has filled all the carious cavities, he thinks his work is done. He should be able to group the whole pathologic picture and know the relation of conditions in the mouth to other conditions of the body which require medical treatment, in order that he may intelligently call in counsel or refer the patient to some one capable of caring for him. In other words, he must be able at least to make a probable diagnosis of the case in general, just as in medicine, it is not enough that a physician make a diagnosis of pulmonary tuberculosis; he must be able to say how far advanced it is; he must know the condition of the digestive and eliminative organs, what complications exist, whether the patient is a menace to the health of others, or not. Tersely, he must be able to make a complete diagnosis.

The dentist should have courses in physical diagnosis, both clinical and laboratory. His experience in handling patients in the free dispensary of the medical school will be of inestimable value to him in handling his own dental patients. Only by actual work in inspection, palpation, percussion and auscultation on patients suffering from various diseases will he be able to grasp the whole picture and become familiar with the living pathology of the mouth, and see its connection with general pathologic conditions. If he fails in this, his medical degree and the time taken to attain it have been for naught.

Dr. Eugene S. Talbot, Chicago: I am surprised and pleased at the unity of opinion expressed by the able teachers coming from different parts of the country and occupying such varied positions in the teaching world both in medicine and dentistry. On one point all agree and that is all dentists should be stomatologists practicing under a medical degree. All seem to agree that the medical course should be so arranged that the fundamentals of medicine should be the foundation on which to build all specialties. First obtain the medical degree and the specialties studied afterward. This will place all specialties on an equal footing. This method seems reasonable and easy to accomplish.

Like the medical schools in this country, there are more dental schools than can exist. There is no need of more than one school in a state. Let the weaker schools unite with the stronger or disband. About fifty-four medical schools have either given up or joined stronger and better equipped schools in the past five years. Twenty or twenty-five dental schools can go out of existence and never be missed. Let twenty-five of the best schools become actual departments of universities and an ideal specialty can thereby be developed.

INTERMITTENT CLOSING OF RETINAL ARTERIES *

ARNOLD KNAPP, M.D.
NEW YORK

Disturbances of the retinal circulation causing loss of vision are exceedingly complex, and are still imperfectly understood. There are unquestionably some conditions which are not due to embolism or thrombosis. Temporary obscurations are not infrequent clinical manifestations of a disturbed retinal circulation, and they often precede permanent, partial or complete blindness.

These attacks of temporary obscuration were formerly attributed to embolism; the plug supposedly at first obstructed the main trunk of the retinal artery, and later lodged in a branch (Graefe, Mauthner, Schnabel and Sachs). This theory was later abandoned, because of the number of recurring attacks without any evidence of the subsequent fate of the embolus (Loring, Wagenmann).

According to Ole Bull,[1] Zehender was the first to draw attention to vessel cramp as a cause for sudden amblyopia and amaurosis. Benson[2] has reported on a case of intermittent obscurations in which he examined the patient during an attack and found the inferior temporal artery to be bloodless. This condition promptly disappeared, and later the ophthalmoscopic examination gave almost negative results. Dr. Benson thought that spasm probably determined the attacks. Wagenmann[3] examined a patient with recurring obscurations

during an attack and found both arteries and veins contracted. Iridectomy checked the process for seven months; then an attack with permanent blindness supervened. This author believes that the attacks can only be explained by vascular spasm, the local cause being arteriosclerosis. Galezowski has directed attention to the positive existence of vascular spasm of the retinal arteries and its relation to arterial thrombosis. Ole Bull[1] believes that angioneurosis may be as frequent a cause for circulatory disturbances in the retinal vessels as embolism or thrombosis, and that all cases of obscurations are due to cramp, especially as spasm is likely to occur when pathologic vessel changes are present and often leads to a thrombus formation. Osler[4] states that in certain stages of arteriosclerosis arteries are very prone to spasm.

Russell,[5] in a paper on "Intermittent Closing of Cerebral Arteries," suggests the term closing to express this vessel action and describes loss of brain power from intermittent closing of cerebral arteries (temporary paralysis) as it takes part in the production of permanent paralysis. This closing is caused by vessel changes effected by means of the muscular coat; it is partial or complete, producing impairment or complete suspension of function.

As examples of local closing there is the local syncope of Raynaud's disease. Raynaud[6] states that he observed a cramp of the retinal vessels in the sickness which bears his name, but Panas,[7] at Raynaud's request, examined some of his patients and failed to find any difference in the caliber of the vessels during the access of asphyxia. The contraction of retinal vessels in this condition has, however, been found by a number of other observers.

In this group of vasomotor phenomena belong contractions of the retinal artery in epilepsy, malaria, whooping cough and migraine.

As examples of local closing in diseased retinal arteries I wish briefly to report the following cases:

CASE 1.—J. B., male, aged 66, was first seen on Aug. 18, 1909, with acute glaucoma in both eyes. The vision in the right eye was 5/200; in the left m. h. Tension was very much increased in both eyes. The man had suffered from prodromal glaucomatous attacks in the right eye for one year and a gradual contraction of the nasal field in the left eye.

Treatment.—He was prepared for operation by eserin, leeches and cathartics. The tension was reduced, and vision in the right eye was 20/70; field normal. In the left it equalled 20/200; the field was contracted to an oval in the temporal half of the field. Iridectomy was performed on both eyes under ether without accident.

Result.—At the first dressing the patient claimed that he could not see with his left eye. The condition remained unchanged though the tension in both eyes was normal and the healing smooth. Ophthalmoscopic examination of the left eye revealed an atrophic disc, no cup, no hemorrhage, but the retinal artery was very narrow, with variations in caliber and white sheaths. Vision was reduced to faintest light preception. The right eye sees 20/30; field is slightly contracted nasally and below. The disc is pale; no cup; distinct endarteritis. The patient showed organic cardiac lesions, general arteriosclerosis and senile paraplegia.

In this case the sight in the left eye was lost after an operation through no fault of the operation or treatment. A plausible explanation seems to me to be that the already narrowed blood vessel in the left eye through some nervous or unknown influence became closed for a sufficient length of time to cause permanent loss of sight. It is another example of the interdependence of glaucoma and arteriosclerosis.

CASE 2.—R. B., aged 53, was first seen on Jan. 29, 1910. Eighteen months ago the vision in the left eye failed suddenly, then improved somewhat, though at present there is only light perception in temporal field. Recently, after severe right hemicrania for four weeks sudden loss of sight occurred in the right eye; after one and one-half hours vision returned.

Examination.—Right eye: pupil was normal; vision 20/100; field normal; retina edematous. The veins were full; the arteries distinctly narrowed. Left eye: disc white; veins tortuous; arteries very narrow. Urine was normal. There were chronic cardiac hypertrophy (valvular lesions), and arteriosclerosis. Blood pressure was $\frac{\text{V. } 265}{\text{H. } 260}$; pulse $\frac{\text{V. } 76}{\text{H. } 64}$; apex beat 5½ inches to left of middle line in fifth space. Sounds at apex were of equal intensity.

Subsequent History.—The patient has been taking nitroglycerin and iodid of potassium. On March 9, 1910, right vision was 20/50; disc normal; veins tortuous, irregular outline; indented; arteries tortuous; often abruptly narrow and nearly invisible; no perivasculitis; one small hemorrhage. Left eye: vision m. h.; disc atrophic; arteries very contracted, often invisible.

Without any periods of obscuration in a patient with general and retinal arteriosclerosis the vision was lost suddenly in the left eye; the condition has remained unchanged. One and one-half years later the vision in the right eye was lost for one hour and a half, and was then regained.

CASE 3.—R. L., aged 32, for many years had periods of obscuration occupying either lower or upper half of field, varying in either eye; only one eye at a time was affected. These attacks would last five minutes. The patient suffers often from headache, nausea and vomiting.

Aug. 20, 1909: Present attack began six weeks ago and loss of vision has persisted. Right eye: lower half of field is defective. Superior retinal artery is very thin, with a faint red line; it resembles a wax cast. At a short distance from the disc the caliber of the artery becomes normal.

Nov. 2, 1909: The patient has had several attacks of temporary obscuration in left eye since right eye was affected. There is apparently no cause for these attacks. The upper half of the field is always involved. The inferior retinal artery is full, rounded, hard; no indentation of veins.

In this patient after periods of obscurations the sight in the lower half of the field in one eye was permanently lost, and there have since been some attacks in the upper half of the field in the remaining eye.

CASE 4.—C. A. L., aged 60, has general arteriosclerosis, and was first seen on Sept. 21, 1909. Recently there was sudden loss of vision in the right eye, which gradually improved. Now vision is 10/200; retina edematous; marked constriction of arteries; veins full; relative defect in nasal field.

October 27: R. 20/40. Five days later, after mental excitement, there was another attack of blindness principally in right nasal field which passed off.

Jan. 5, 1910: R. 20/30. Inferior temporal artery is distinctly obliterated at one point. Both superior and inferior temporal arteries show caliber variations.

The sight was suddenly lost in one eye and then gradually regained. Subsequently after an emotional outbreak vision was again temporarily obscured in the same eye.

CASE 5.—M S., aged 63, had had no previous obscurations. There was marked general arteriosclerosis.

October 23: After headache and vomiting, was totally blind on awakening. There was no history of having taken any drugs or wood alcohol. Pupils were fully dilated; there was retinal edema. Arteries were small, veins were changed; no pulsation on pressure; no light perception.

[4] Allbutt's System, Edition 2, vi, 627.
[5] Brit. Med. Jour., Oct. 16, 1909.
[6] Quoted from Dufour, Encyclop. Française d'Ophthal., vi, 117.
[7] Traité des maladies des yeux, i, 619.

October 26: General return of pupillary reaction, light perception in temporal field. Arteries remain very small.

October 30: R. 4/200; L. 2/200; retinal edema; optic discs pale; arteries thin and outlined in white. Gradual deterioration.

December 16: R. 2/200; L. 1/200. Field showed concentric contraction.

January 1: Pupils wide; irresponsive; R. m. h. in temporal field; L. = O.; arteries invisible; optic disc atrophic.

March 1: Patient totally blind; arteries invisible for short distance from disc.

November 1: R. glaucoma T. +.

In this case both eyes were simultaneously affected. There was at first some return of vision, which, however, was completely lost after three months. The ophthalmoscope showed at first retinal edema and narrowed arteries; later optic atrophy with obliterated and sclerosed vessels.

Intermittent closing of healthy retinal arteries may occur without any lasting effect on vision. In diseased retinal vessels this phenomenon is of grave significance, as the vessel may remain obstructed or lead to thrombosis. In subjects with retinal arteriosclerosis, especially if obscurations have been present, a rigid general treatment of the arteriosclerosis should be given, mainly with a view of preventing any of the causes which seem to contribute to closing of the arteries.

26 West Fortieth Street.

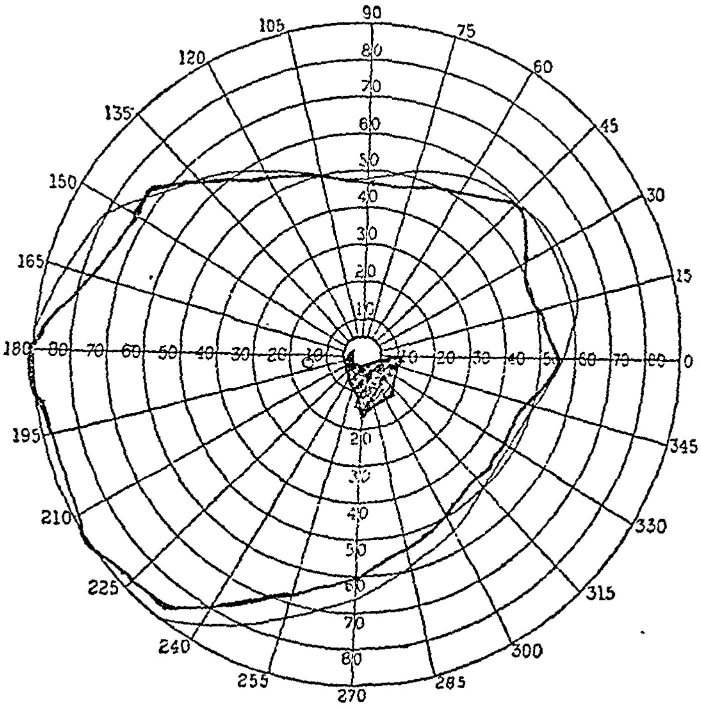
ABSTRACT OF DISCUSSION

Dr. W. C. Posey, Philadelphia: In a paper entitled "Transient Monocular Blindness," which I read before the College of Physicians in 1902, I reported a series of cases similar to those described by Dr. Knapp. Dr. Knapp states that Ole Bull gives credit to Zehender for being the first to draw attention to vessel cramp as a cause for sudden amblyopia and amaurosis, but fails to mention the date at which this observation was made. As far as I could judge from the study of the literature, Loring, in 1874, was the first to make any extensive communication on the subject of transient attacks of blindness, although Alfred Graefe, Hedaeus, Rothmond, Secundi, and others had reported isolated cases, where this symptom had occurred in connection with excessive reduction in the diameter of the retinal arteries. Loring based his study on the observation of five cases, in all of which symptoms previously ascribed to embolism of the central artery of the retina were present. This origin of the blindness, however, he disputed and concluded that, in the train of symptoms classed under the title of embolism, too much significance had been given to the stoppage of the circulation by the lodgment of a plug formed at a distance from the eye, while not enough stress had been laid on the mechanical actions regulating the supply of the blood within the eye, as well as on the condition of the walls of the vessels themselves and their contents.

I pointed out in my paper that the prognosis in these cases should always be guarded, and cited a case in which a probable thrombosis of the central artery of the retina occurred in an eye which had been the seat of some fifteen to twenty attacks of transient blindness extending over a period of eighteen months.

An observation of very great interest in connection with these cases, both from pathologic and physiologic standpoints, is one made by Leber, of a case of monocular blindness in which there were all the ophthalmic signs of embolus but in which the microscope failed later to reveal any evidence of either embolism or thrombosis. Leber attributed the blindness and the pathologic findings to long-continued spasm pure and simple. The course of this case, until the final attack came and vision was hopelessly lost, was precisely analogous to the apparently innocent group of transient blindness. It is evident, therefore, that the prognosis in all of these cases of transient blindness should be most guarded, as it would appear impossible to predict what the outcome of any one of them might be, whether the blindness be due to spasm and be always transient, whether it be due to a forming embolism which finally destroys the sight by shutting off the blood-supply entirely, or whether the same fatal result is attained as in the case reported by Leber, by long-continued spasm, without microscopic change in the vessel walls.

Dr. E. C. Ellett, Memphis: Four of the patients whose cases are reported in the paper are elderly people with gross vascular disease. Case 3 is in a young person, without vascular disease. These should, it would seem, be taken to represent different conditions, one functional, the other organic in nature. The commoner type, as indicated in the paper, is that seen in old people with arteriosclerosis, and appears under the form usually described as embolism, and about whose exact nature much uncertainty exists. It is significant that complete recovery rarely follows these attacks, as indicated by the ophthalmoscopic changes and visual disturbance which continued to be present in the cases reported. A case, the exact nature of which is not clear to me, has recently come under my notice.



Left eye, Mrs. E., March 15, 1910.

Mrs. E., aged 35, woke on the morning of Jan. 20, 1910, to find that her left eye was blind. I examined her about 8:30, and found the blood current in the arteries interrupted, there being stretches of empty vessels, then a column of blood, and then empty vessel. This affected all the arteries. There was edema of the retina, cherry spot at macula, and slight fullness of the veins. Amyl nitrite was at once administered, with deep massage and later erythrol tetranitrate and small doses of mercury. The vision began to return in twenty minutes, and gradually improved. On April 19 she saw 20/25 p, excubically, and the field was as shown on the attached chart. This patient's general condition is interesting. I have known her from childhood and she is and has always been intensely anemic. She has metrorrhagia due to fibroids, which probably explain her anemia. About a year ago her blood showed a marked grade of chlorotic anemia. At the time of this attack her blood showed 65 per cent. of hemoglobin, 5,200,000 red cells, that is to say chlorosis. She also has mitral regurgitation; hemiopia and other forms of visual obscurity are part of the picture of ophthalmic migraine and temporary obscuration, without headache is more common. I have two cases of the latter type in mind in which I can only speculate as to the cause, since I have never been able to examine either of them in an attack. At other times the vision and eye-grounds are normal.

Dr. L. Connor, Detroit: Three or four years ago I reported some observations on the use of vibratory massage on the eye. One was the following: A man, aged about 50, three months before coming under my care, began to lose his sight. He had been in the hands of one competent oculist after another and the refraction of the eye had been perfectly determined. The only abnormal condition to be found was a cord-like condition of the retinal arteries. I thought that the patient had had everything possible done for him; but I had already demonstrated by the use of the vibratory apparatus in the normal eye that I was able to reduce the size of the retinal artery. The patient's vision for distance in one eye was 12/200 and the other about 8/200. He was unable to read and was incapacitated from work. It occurred to me that what I had learned might have application here. His kidneys, liver and digestion, and every other function, so far as experts could determine, were quite normal. I passed this instrument around the sclerocorneal junction of each eye for a minute and repeated the operation, and within five minutes the patient could read 22/100 with one eye and with the other 18/200. I looked in the eye and found that the size of the arteries was perceptibly larger, and there was the increased vision. So I determined to continue the treatment. There was a progressive improvement in the vision till within a month the patient could read with his corrected glasses, which did not need any change. At the time I saw him last (three years ago) he could read 20/20 and Jager (Yeager) No. 1. He has been able to carry on his business with entire success since. This is perhaps the most marked example I have met, but there are many other cases allied to this that I have been unable to reach in any other way.

DR. W. ZENTMAYER, Philadelphia: Five years ago I presented this subject of spasm of the central artery of the retina before this section on the basis of one case which I had seen in consultation. A man had repeated attacks of transsient, monocular blindness, occurring over a period of two or three days. Only on one occasion did it affect both eyes. He had as many as ten or fifteen attacks in an hour. It is now five years since the attack and he has never had a recurrence. Some time afterward Dr. DeSchweinitz read a paper on the results of toxemia, and I thought perhaps that case was caused by toxemia. The study of the blood-pressure, at the time of the attacks, however, showed that it was normal and there was no evidence of arteriosclerosis. The interesting fact in connection with the probable cause was that the only treatment which seemed to relieve the spasm was free purgation.

DR. J. L. THOMPSON, Indianapolis: Has anyone ever found this condition in hysterical subjects? We often have it temporarily in these subjects, a day or longer.

DR. M. FEINGOLD, New Orleans: Dr. Knapp makes a correct distinction in these cases between cases based entirely on spasm and those based on thrombosis, or embolism. But I wish to recite a case in which this sharp distinction cannot be drawn. Several months ago a man of 74 called at my office. I had examined his vision and prescribed glasses a year before. He had been sitting at luncheon when he suddenly became blind in one eye. I examined him and found his vision, which was 5/30 a year ago was now 5/12, and he could read only the right end of the line. He could not see the left end. The other changes were practically *nil*, except that the disc in the left was paler than in the right eye. The arteries were distinctly visible, but possibly narrower. The veins were well filled. The eye was practically normal except for the paleness of the disc. Acting on what has been recommended by others I told the patient to go home and take a free purge and come back the next morning. This man has been long under treatment for severe arteriosclerosis. The next morning he could see 5/30, the whole line. I ordered the purgation to continue and ordered sodium iodid, and in the course of four or five days the vision returned to the normal condition, and the left disc became almost of the same color as the right. This is one of those border-line cases which we cannot distinctly define as due to thrombosis or embolism or to spasm simply; because we know thrombosis can be of such a character that it will allow a certain amount of blood to flow through. The circulation in this case was thoroughly reestablished in the course of a few days.

DR. W. REBER, Philadelphia: I take it that thrombosis can take place without evidence of gross lesion. In the class of cases in which there is no gross lesion we do not and we cannot to-day, except clinically, distinguish between spasm and thrombosis; but in those in which there is no thrombosis and in which there is transient monocular blindness, such as those described, the indications all point to toxemia. And I am firmly convinced that, as Dr. Knapp has said, transient blindness, monocular, is always a grave sign; very much graver in the presence of an altered blood-pressure; grave enough though the blood-pressure may be negative. I should be worried if I were subject to one attack of transient monocular blindness. The treatment is eliminative, as in the two cases cited. Nothing was of any avail until the patients were purged with Epsom salts and water taken by way of the intestine or by way of diaphoresis. The best possible elimination in such cases is none too good.

DR. W. HAUGHEY, Battle Creek, Mich.:—I should like to report a case I had three weeks ago. The patient is a man of 24, who when a boy was an athlete, always running. He spent some time in the South, where he acquired the habit of smoking to excess and drinking strong black coffee clear. He had a very small refractive error in both eyes, which I corrected about a year ago. Three or four months ago he came to me with a sudden partial blindness in the right eye. He had 22/100 vision. I could see the retina and found dilated vessels of the retina, which were small, and the heart action was about as irregular as any I ever heard. The patient would have missed beats and delayed beats, etc., but no particular valvular difficulty. He had steadily improved under eliminative treatment. This trouble was only in one eye and I found it was toxic from tobacco or coffee. He has discontinued them both, and with strong eliminative treatment he is improving.

DR. A. GREENWOOD, Boston: I want to add my testimony to that of Dr. Knapp that these conditions must be looked on as very grave when they occur in patients with high arterial blood-pressure. Some years ago at Atlantic City I read a paper on obstruction of the retinal arteries, and have been interested in them since. I feel very strongly that these cases must be watched with the greatest care, and that everything that can be done must be done to reduce the blood-pressure where it has been raised. It has been my experience that the blood-pressure has been raised in all cases, even in people under 40. In the present day of high living in America there is no question that we find advanced arteriosclerosis even in the younger generation, and I think this condition requires the greatest care on the part of the ophthalmologist and also on the part of the family physician.

DR. ARNOLD KNAPP, New York: As far as I remember Dr. Ole Bull mentioned this first in 1857. He mentions Raynaud's observations, so that the condition must have been familiar. None of these patients were hysterical. In fact, in hysteria the most important feature has been the normal condition of the eye-ground. The exciting cause of the spasm is an interesting question, but it is complex. I want to emphasize the importance of preventive treatment, because I think treatment after the condition has occurred is nearly always unsatisfactory.

ACUTE GONORRHEAL SALPINGITIS

HENRY B. ORTON, M.D.
EAST ORANGE, N. J.

It is the primary purpose of this paper to report a case of acute gonorrheal salpingitis cured by the injection of antigonococcic serum, but a few words regarding the ascension of gonorrheal infection in women will not, I trust be out of place. Extension to the appendages is estimated to occur in from 13 to 20 per cent. (Bunn). The ascent of infection from cervix to fundus, and fundus to the appendages, is usually favored by some contributing cause such as sexual excess (especially in close relation with the menstrual period), alcoholism; run-down system, abortion and labor, septic instruments, and continued cohabitation with an infected male. The vagina in adults is covered with thick stratified epithelium which resists the infection, making gonorrheal vaginitis a rather rare condition, although a secondary vaginitis may be caused by a virulent cervical discharge passing over the surface. I am not writing a treatise on the pathology of gonorrheal infection, however, but reporting the case from a therapeutic point of view only. I know of only a few cases in which the antigonococcic serum has been used in acute gonorrheal salpingitis, the latest case being that of Dr. Albert T. Tuttle in which he used the gonococcic vaccine. In old chronic cases, especially gonorrheal arthritis, it has been used with marked success.

Patient.—On February 28 I was called to see M. P., aged 20, white, single, who gave me the following history: On February 15 she had intercourse; five days later she experienced frequent and painful micturition, with a little burning in urethra and vulva. On February 22 the menses appeared and continued for three days; then they suddenly ceased for two days, then returned again and continued for one week. On February 26 the patient felt chilly and had severe pains in the head, left iliac fossa and over the pubic bone; with diarrhea, anorexia, nausea and vomiting.

Examination.—On March 5 I made a vaginal examination. The urethra showed a reddened and swollen mucous membrane; the meatus urinarius was red and congested and slightly everted. On pressing the urethra from the vaginal side I could express a few drops of whitish discharge; this I collected on a glass slide and examined for the gonococcus, which I found in large numbers. There was a vaginal discharge; the cervix was reddened and congested and painful to touch. Pain was present over both iliac fossæ but more on the left side; the left tube was enlarged.

Treatment and Course of Disease.—The patient was already in bed. I gave her massa hydrargyri gr. vii followed in the morning by magnesium sulphate. Ice-bag over left iliac fossa, and ordered a douche of tincture of iodin ʒi to a quart of warm water three times a day. On March 12 I injected under aseptic conditions 2 c.c. of the antigonococcic serum. The fever went up in the afternoon after the injection. Again on March 15 and 17 respectively, I injected 2 c.c. more under the same conditions. After the second injection the temperature dropped and has remained down ever since. There was not the least discomfort after any of the injections. I discharged the patient, feeling perfectly well on March 29. She has been in my office three times since for observation and has had no pain, no discharge from either uterus or urethra.

The patient became infected just prior to her menstruation, and, in view of the bacteriologic findings, I can have no doubt as to the diagnosis. She was cured by 6 c.c. of the antigonococcic serum in conjunction with warm iodin vaginal douches. We should give a patient suffering from gonorrheal salpingitis at least three months before thinking of operation. Epididymitis does not require castration. Why then should all cases of gonorrheal salpingitis call for a salpingo-oöphorectomy?

A CASE OF PRIMARY MASTOID PERIOSTITIS

WILLIAM PEARCE COUES, M.D.
Surgeon to the Boston Dispensary
BOSTON

Primary mastoid periostitis is so uncommon that the report of a case is of interest. Blake and Reik[1] say:

> The diseases of the mastoid, which are the most frequent and also the most important from a surgical point of view, are the acute congestions and inflammations secondary to similar processes in the middle ear. A careful study of the few cases of reported primary mastoid inflammations on record suggests, in the light of more recent experiences in this field of clinical investigation, the suspicion that there had been previous middle ear inflammations as the inceptor of a chronic quiescent mastoid disease which was later awakened to acute manifestations, while in others the implication of the mastoid cells possibly followed a superficial periostitis on the outer mastoid surface with pus formation denudation of bone and subsequent spontaneous perforation inward.

History.—F. D., single, aged 20, was seen at the surgical clinic, Boston Dispensary, May 27, 1909. Father and mother, three sisters and one brother, living and well. Patient has had scarlet fever, whooping-cough, measles and tonsillitis. There is no family history of tuberculosis and no history of ear trouble known to patient.

Present Illness.—About one month previous to patient's visit to the dispensary a swelling was noticed posterior to the right ear; it disappeared, but returned, with redness, and with tenderness which was felt at the back of the neck also. Pain extending up to the vertex was present. There was no marked constitutional disturbance.

Examination.—This showed a slight, fairly well-nourished and well-developed girl. The teeth were good; the throat slightly reddened. There was pediculosis capitis. Nothing abnormal was found in the examination of the heart and lungs. There was a rather extensive psoriasis of long standing. Directly over the right mastoid process was a brawny, reddened, infiltrated area, the size of one-half the palm. Posteriorly there seemed to be indistinct fluctuation. The swelling was moderately tender on pressure. No marked cervical adenitis was present. The patient was sent to the aural department of the dispensary for an examination, and the report sent back that the ear was perfectly normal. The case was regarded as one of postauricular abscess, possibly of glandular origin (pediculosis).

Operation.—May 29 ether was given and a slightly curved incision made over the most tender part of the swelling, carried down quite deeply, but not to the bone; no pus found; free bleeding; gauze drain; dressing. There was some relief from pain following the incision. Next day swelling was the same; no pus; redressed with hot boric gauze and drain replaced. The patient did not do well; the cervical part of the swelling, instead of becoming smaller, increased. There was constitutional disturbance.

Second Operation.—The incision was enlarged and a deep cervical abscess opened. A rubber tube was introduced, apparently draining the abscess perfectly. There was now some improvement, but it was not satisfactory. It was noticed at the dressing that pressure on the mastoid increased the flow of pus from the cervical incision, and the patient's consent to further interference was obtained.

Third Operation.—The first part of the former incision was deepened and carried down to the mastoid process; bare bone was seen and felt, but no softened areas were detected suggesting necrosis of mastoid cells. The incision was drained and tube kept in the neck. The patient was seen at home and dressed there. From this time on convalescence was rapid, the cervical abscess drained well, gradually closed and the induration disappeared. The wound over the mastoid cleaned up quickly and covered with granulations, the drain here being soon removed. The patient was discharged well June 22.

Five months afterwards the patient's mother stated that the girl had been well, but that lately the scar had been somewhat reddened. The patient was given instructions to report at the clinic again. and reported in April, 1910. She stated that there had been no recurrence of trouble and that she was perfectly well.

The possibility of a mastoid periostitis, even though two ear examinations showed the ear perfectly normal, should have been thought of and the third operation, which cured the patient, done earlier. No specific history was obtained, but it would have been of interest to have had a Wassermann reaction done in this case.

261 Beacon Street.

ANTITYPHOID VACCINATION

RESULT OF 1,100 INOCULATIONS

FREDERICK M. HARTSOCK, M.D.,
Major, Medical Corps, U. S. Army
FORT WAYNE, MICH.

Antityphoid vaccination by means of the injection of dead typhoid bacilli is now destined to be a practical measure of prophylaxis and of value in the handling of typhoid epidemics.

The adoption of this method of prevention by various foreign military services, as well as our own, and its increasing popularity in the protection of nurses and interns in hospitals, is but a step toward the general use of the vaccine by practitioners at large, and the laity will, I believe, not be backward in seeking this preventive once its value is known and the immediate benign results of the inoculation established.

The method of using the killed bacteria has been placed on a definite and firm basis by Wright by his inoculations in the British Army and in the Boer War.[1] Sufficient time has now elapsed to secure definite statistics on which to base an opinion as to its effect on troops over a long period of time. Wright says:

> The latest statistics are those of Leishman. These statistics cover a period of three years and a half, from the beginning of 1905 to June, 1908. In 5,473 soldiers vaccinated against the disease, 21 took it and 2 died; in 6,610 soldiers practically under the same conditions, who were not vaccinated, there were 187 cases and 26 deaths; that is, among the vaccinated soldiers there were 3.8 cases per thousand, and among the non-vaccinated 28.3 per thousand.

The above difference in the ratios should be sufficient to induce the practitioner to adopt this as a general measure.

The vaccinations, I believe, should be generally adopted for the following classes:

1. All persons between the ages of 15 and 25. Osler states that the greatest susceptibility to typhoid is between these ages.
2. All persons exposed in time of an epidemic.
3. Nurses and physicians.
4. All persons in the military service, and more particularly in time of war, when troops are enrolled and concentrated in camps.

In promulgating this vaccination as a popular measure it is necessary to convince the patient as to its immediate benign effects. The layman must be assured that there will be no detention from business and that the injection is without harm. The military commander, in time of war, when troops are being mustered in, must be convinced that his forces will be ready for duty at any time. I believe that my series of 1,100 vaccinations will give sufficient evidence to assure affirmatively both the above.

Of this series there were 1,100 inoculations in 563 persons. The ages ranged from 15 years up, but mostly those of military age—from 21 to 35 years.

The vaccine used was furnished from the laboratory of the Surgeon-General's office, U. S. Army, and to most cases two doses were administered; first inoculation, 500,000,000 bacteria; second inoculation, 1,000,000,000 bacteria, and the third inoculation, the same number. Injection by means of the ordinary hypodermic syringe was employed, and given either at the insertion of the deltoid or in the flank. The latter is the more painful and should not be employed.

The classification of reactions is that adopted by the Medical Department, U. S. Army, as follows:

> Reaction, none; mild, temperature up to 100; moderate, temperature up to 103; severe, temperature above 103.

To this I desire to add that in cases quoted as presenting no reaction all patients had a very slight local tenderness and redness at point of inoculation. In cases cited as mild the patients had slight general reaction; malaise and considerable local tenderness. In cases cited as moderate the patients had considerable general reaction; added to fever were nausea, rigor, muscular pains, headache and indisposition for about twelve hours; and in the severe local reaction causing disuse of arm for twelve hours, and all stated they were "very sick."

No untoward results were noted; all patients recovered promptly and in the severe cases the patients were able to attend to duty after twenty-four hours. A small percentage of patients had severe rigors, slight general erythema, diarrhea and vertigo, and one had epistaxis.

The figures are as follows:

TABLE 1.—REACTION IN 562 CASES

	First Dose.		Second Dose.		Third Dose.	
	No.	%	No.	%	No.	%
None	55	9.8	66	12	1	50
Mild	471	83.7	436	81	1	50
Moderate	31	5.5	29	6	..	..
Severe	6	0.1	4	1	..	..
Total	563		535		2	

In the 563 cases, 56 men stated that they had previously had typhoid fever. On these the percentage of reactions was as follows:

TABLE 2.—REACTION IN 56 CASES WITH A PREVIOUS TYPHOID

	First Dose.		Second Dose.	
	No.	%	No.	%
None	10	17.8	9	16
Mild	41	73.3	42	79
Moderate	5	8.9	3	5
Severe	None		None	
Total	56		54	

Of the 1,100 vaccinations the reactions were as follows:

None	122	or	11	per cent.
Mild	908	or	83	per cent.
Moderate	60	or	05	per cent.
Severe	10	or	.001	per cent.

From the above it may be noted that the reactions differ but little between the first and second doses and that the typhoid cases react in no way differently than the non-infected.

INTEGUMENT ATROPHY: A SIGN OF DIAGNOSTIC IMPORTANCE IN EARLY PULMONARY TUBERCULOSIS

PRELIMINARY REPORT

CLARENCE L. WHEATON, M.D.
Physician with Chicago Tuberculosis Institute and Central Free Dispensary, Rush Medical College
CHICAGO

Attention is called to a new sign which I believe to be of considerable diagnostic value in the examination of those afflicted with pulmonary tuberculosis. In a considerable number of tuberculous patients examined at the Rush Medical College it was observed that the integument or skin when picked or pulled away from the fascia was, over certain areas freely movable and not adherent to the muscle fascia. This phenomena was especially noticeable in cases of early unilateral involvement, and subsequent exa[illegible] showed the tuberculous process to be on the [illegible] we could elicit the sign. Now if there is bilateral involvement the sign can be demonstrated on both sides but will be more pronounced over the original area of infiltration.

METHOD OF ELICITING THE SIGN

The patient with hands resting in the lap faces the physician, looking straight to the front. The integument is then pinched between the thumb and index-finger and pulled away from the muscle fascia. It will be observed that over the area of infiltration the integument can be drawn from the chest wall with ease as compared with the side where there is healthy lung, and if now rolled between the fingers it will feel in consistency much thinner than a fold of skin taken from the sound side.

This condition or change in the integument of the chest wall has been observed in very early cases of tuberculous infiltration with little disentegration of the lung in both adults and children. Whether this is a true atrophy of the skin or due to muscle or nerve degeneration, or in some measure dependent on immobility of the chest wall I am at this time unable to say. It is suggested that this sign be sought as the first step in the examination of the patient, and the lesion within the lung then demonstrated by the usual methods. The value of the sign is in the fact that this atrophic change occurs early, and before there is extensive disintegration of the lung. Numerous colleagues having confirmed my findings, I now present this preliminary report, trusting that my observations may be found correct by others, and this contribution prove an aid in the early diagnosis of pulmonary tuberculosis.

2738 Pine Grove Avenue.

INJECTION OF PARAFFIN INTO THE APPENDIX IN AN ATTEMPT TO CURE INDIRECT INGUINAL HERNIA

REPORT OF A CASE

A. C. STOKES, M.D.
OMAHA, NEB.

History.—Mr. V. was referred to me by Dr. Miller of Gibbon, Neb., Jan. 19, 1909. He was of German birth and a farmer by occupation. The family and personal history were negative, except that the patient had suffered with an indirect inguinal hernia for a few years. About ten days previous to visiting us he consulted an irregular practitioner in Omaha for his hernia. This physician agreed to cure him, without operating, by an injection method. The patient underwent the injection on Saturday and returned to his home, about 120 miles away, the same day. On Monday he was taken with severe pains in his right side, which were diagnosed by his home physician as due to appendicitis. He was referred to us for operation.

Examination.—The attack did not seem to be typical appendicitis and we kept him under observation for about two days before operating. He was running a temperature of about 99 to 100 F., no increase in pulse, slight rigidity over the right rectus, no gastric symptoms, and in fact no other symptoms which could be located. The blood-count was 7,200 whites, 4,200,000 reds, no polynuclear increase, and no signs of infection; but the pain and soreness continued. We therefore decided to operate.

Operation and Course.—We made the usual incision over the rectus muscle, found the appendix considerably inflamed, very hard, and the hardness extending over the cecum. We removed the appendix and cecal base of the appendix, suspecting that it was cancerous. On examination of the part removed it seemed to be filled with a hard waxlike substance. Microscopic examination showed the material to be paraffin. The presence of the paraffin in the appendix had caused the pain. The man made an absolutely uninterrupted recovery, and our pathologist, Dr. Wooley, now of Cincinnati, reported the appendix to be free from carcinomatous infiltration. The patient is still absolutely well after nearly a year and a half.

We could not tell exactly where the paraffin entered the appendix, whether immediately into its lumen, or, probably, beneath the serous covering.

In injecting the hernia the physician probably passed the needle below the canal into the appendix, or into the cecum about the appendix, and infiltrated this area.

It seems such an uncommon and unexpected occurrence that it is worth reporting.

Brandeis Building.

ALUM BATHS IN TYPHOID FEVER

A PROPHYLACTIC AGAINST SKIN INFECTION

THOMAS R. BOGGS, M.D.
Resident Physician, The Johns Hopkins Hospital
BALTIMORE

Various forms of skin infection have been commonly associated with typhoid fever from the first recognition of the disease. In the older studies a very large proportion of all patients had boils, bed-sores or abscesses during the later weeks or in convalescence. With the advance in nursing methods and general hygiene in the past quarter century, the incidence of these complications has been greatly reduced, but there is still a rather constant percentage of skin infection in the very best hospitals where especial attention is given to the care of the skin. That is, in spite of alcohol rubs, frequent turning, and changing bed-linen, with liberal use of dusting powders, we still have more furunculosis and decubital sores than we should.

This constant appearance of skin complications has been attributed in part to the wide prevalence of the Brand treatment of bathing the patients in tubs. It is true that such bathing at frequent intervals (every three or four hours during the fastigium of the disease) does tend to soften the skin and render it less resistant. Again, the patients frequently void infected urine or feces in the tub during the bath, thus increasing the bacterial flora of the skin. Furthermore, the constant rubbing of the skin during the bath, which is essential to the best therapeutic results, leads to a certain amount of irritation, particularly about the hair follicles, and marked in proportion to the hairiness of the skin.

In the large typhoid experience in this hospital we have sought, in every way possible, to minimize the skin infection by the most scrupulous care, the skin of each patient being examined daily. In addition to the general measures for keeping the skin dry and smooth, we have covered the long rubber gloves worn by the nurse with a mitt of toweling in order to prevent the pulling of the body hairs by the wet rubber. Nevertheless, we have had, during the last ten years, a fairly constant percentage of skin infections, counting all furuncles, abscesses, folliculitis, dermatitis, and bed-sores.

It occurred to me that something might be accomplished by the use of antiseptics in the bath-water or some further means might be taken to increase the resistance of the skin. For this purpose a non-irritating and non-poisonous material must be chosen and one not too expensive. After some investigation, commercial alum (potassium aluminum sulphate) was selected. This substance is readily soluble, has fairly strong antiseptic properties (see Sternberg's tables) and, as is well known, tends to precipitate organic matter in water. In addition to these, it exerts some tanning, or hardening, influence on the skin—and, lastly, it is cheap.

For two years we have used it as a routine in our wards and, as the results seem encouraging, it is brought to the attention of the profession in the hope it may prove generally useful.

The procedure is very simple and is carried out as follows: One pound (500 gm.) of powdered alum is quickly dissolved in a little hot water and added to the tub during the filling. With the average tub of 450 to 500 liters, this makes approximately a 1 to 1000 solution. The alum is sent to the ward from the pharmacy in pound packages, so that the time for preparing the bath is not appreciably lengthened. The cost is about 4 cents per bath.

The patient is bathed in the alum solution just as in ordinary water and experiences no inconvenience from the presence of the drug. The only noteworthy changes in the skin are a slight increase in desquamation during convalescence and a decided diminution in the incidence of skin complications of all sorts (amounting to 50 per cent.) as shown by the tables appended. In these cases the care of the skin is the same in all except for the alum baths. It is not suggested that the alum baths can replace the rigid care of the skin in the ordinary way, but that with them the frequency of skin complications may be still further reduced.

RESULTS OF ALUM BATHS IN PREVENTING SKIN INFECTIONS IN TYPHOID

Cases Treated.	Abscesses.	Furunculosis.	Bed Sores.	Dermatitis.	Folliculitis.	Total Skin Infections.	Percentage.

* Six cases are excluded in which patients received only sponge baths without alum.

Therapeutics

DIET IN GOUT

The relationship of gout to uric acid and uric acid to gout is of perennial interest and furnishes a subject for continued discussion. An increase of uric acid in the blood or uric acid derivatives in the blood during gout is generally understood to be a fact. Consequently, any diet that will diminish the amount of this substance in the blood should be of benefit in this disease.

Schittenhelm (*Therap. Monatshefte,* 1910, xxiv, 3, 113) believes that the first point of attack in the rational treatment of gout is the uric acid circulating in the blood, *i. e.,* the uricemia. He believes that just as it is necessary in diabetes to keep the patient on a non-sugar yielding diet for several months or even years, it is necessary to prevent a gouty patient from eating purin-yielding food. Schittenhelm believes that by prolonged care in the diet most cases of uricemia not complicated by diseased kidneys can be cured. Of course it should be remembered that some of the uric acid in the blood comes from the breaking down, within the body, of white blood cells and other nuclein containing tissues, but the purin-free diet must reduce the uric acid salts in the blood.

Meats and flesh of all kinds, even fish, contain purin bases, and to prevent uric acid from being formed from the diet, flesh of all kinds must be prohibited. It has long been known that foods that are rich in purins, such as liver, pancreas, thymus, brain, or other sweetbread titbits, shad roe or the roe of other fish, should be excluded from the diet of a gouty patient. It has now for several years been known that alcohol in any form taken with an ordinary meat meal would increase, probably by its action on the liver, the formation of uric acid. Consequently, alcohol in any form should not be allowed to patients with a meal which contains meat, even if alcohol is allowed between meals, or with other foods.

It has also been a question of discussion as to the fate in the body of methylpurins ingested with tea and coffee. The purin derivatives in these beverages are caffein, theobromin and theophyllin. Besser (*Die Therapie der Gegenwart,* 1909, l, 321) has recently published the results of investigations by him on the metabolism of these methylpurins in which he finds that the uric acid excretion by normal man is slightly increased after the administration of tea or of coffee.

These findings by Besser are contrary to the results of investigations by many others, they claiming that a part of these methylpurins are demethylated in the body with the production of monomethylxanthin. On account of these contradictory findings in regard to an increase of uric acid from tea and coffee, Schittenhelm made investigations both chemically and physiologically which seemed to prove that demethylation of these methylpurins was perhaps impossible, and secondly, that in dogs uric acid was increased by the administration of caffein and theobromin.

From these experiments it therefore would seem, that an increase of uric-acid combinations, and perhaps its progenitors, in the blood is an aggravator of gout, and that tea and coffee should be excluded from the dietary of gouty patients.

International Hospital in Turkey.—An international hospital has been opened in Adana, Turkey, such an institution being the most pressing need after the massacre which entailed a great deal of sickness and suffering. The city has a permanent population of nearly 70,000, and this is the only hospital in the district, except one for the Turkish soldiers. Major Doughty-Wylie, the British consul, says: "Nothing in the way of charitable effort has been done in this country more worthy of generous support, nothing more acceptable to all races and creeds." There will always be private wards and special care for Americans and other foreigners. There are often cases of serious illness among tourists, or among foreign workmen sent out to set up new machinery, and the only accommodations for such patients are in the private homes of missionaries. A leading German firm, which has several of its own men in Adana, is actively interested in the hospital. The nurses are mainly British. The American Board, which has been at work in Turkey for more than half a century, will be responsible for outfit and traveling expenses if the right man can be found to be at the head of this important work, and an American woman has pledged one-quarter of such a man's salary for two years. If Adana were in the condition that it was before the massacre there would be a good revenue from fees, but the present desolation makes this source of income small.

SATURDAY, JUNE 25, 1910

[The large amount of space occupied by the index this week makes it necessary to omit some departments and to curtail others.]

THE INDEX

One of the important "features" of The Journal is the Index accompanying each semi-annual volume, which appears in this issue. By degrees the importance and great practical value of this index to those who desire to look up medical literature is being realized more fully; yet we fear that even now comparatively few of our readers appreciate its full value.

The work connected with preparing this index, from both the literary and the mechanical viewpoints, is enormous. We emphasize again the fact that this index is not only an index of the matter that appears in The Journal, and in that respect possibly no better than similar indexes in other weekly journals, but also an index to practically all the original articles published in the leading domestic and foreign medical journals during the preceding half year. It is, in fact, an index of the world's most important medical literature. To make it of value the articles are indexed not only under their titles, but also by cross-references to subjects.

In our Department of Current Medical Literature are listed more than 100 domestic journals, and nearly as many foreign. This includes 24 weeklies, 10 biweeklies, over 100 monthlies, 15 bimonthlies, 16 quarterlies and over a dozen periodicals published at irregular intervals. The special value of the index comes from the fact that it is up to date, so that, while it does not compare in detail with the *Index Medicus* or with the Index of the Surgeon-General's Library, it has the very great advantage of containing references to current literature.

To increase its usefulness and to make it easy of reference, the index is also published in pamphlet form, with the titles given. The advantage of this pamphlet, the "Guide to Current Medical Literature,"* is that references can be looked up without handling the large bound volumes or many single numbers.

FOURTH-OF-JULY INJURIES AND PROPHYLAXIS

For seven years The Journal has been collecting statistics regarding deaths and injuries resulting from the celebration of the Fourth of July. These statistics are based on definite information obtained from reliable sources. From these, tabulations were made and published in such form as to be clearly understood by the public, as well as by the medical profession. For three or four years little attention was given to this matter by the press, and, consequently, it seemed as though the labor was in vain. Reprints of these tabulated statistics were made and their distribution was gradually made wider, so as to include not only the leading newspapers, but officials connected with most of the municipal governments. At first only the Chicago newspapers, especially the *Tribune,* made mention of the report, but during the last year or two these reports have been utilized in articles and editorials not only by the leading newspapers, but by all classes of magazines. Finally the public has become thoroughly aroused. A strong public sentiment has been created in opposition to the former inhuman methods of celebration, and in their place are being substituted pageants, parades, flag drills, picnics, and the like. Probably no single work undertaken by The Journal has resulted in so much direct good to the public as has this annual presentation of Fourth-of-July casualties. In the collection of the data each year, we have had the cooperation of an increasing number of physicians, and we hope that this cooperation will be still more extensive this year. We trust that every physician who has a case of Fourth-of-July injury will report it to us. All we want is a brief mention of the actual injury, the immediate cause and the result; we desire particularly to know the kind of cartridge or fireworks used. May we again take the opportunity of urging on physicians the importance of prompt and thorough treatment of these injuries, especially so that the harmful results of lockjaw may be avoided? We offer the following simple rules to be followed in the treatment of every blank-cartridge or puncture wound:

TO PREVENT LOCKJAW

1. Inject subcutaneously 1,500 units of antitetanic serum and continue the injections if indications of possible tetanus arise.
2. Freely incise every wound.
3. Carefully and thoroughly remove from the wound every particle of foreign matter.
4. Cauterize the wound thoroughly with a 25 per cent. solution of phenol (carbolic acid) in glycerin or alcohol.
5. Apply a loose, wet boric acid pack.
6. In no case should the wound be closed. It should be allowed to heal by granulation. The dressing and packing should be removed every day, and fresh dressings applied.

Medical News

CALIFORNIA

Commencement Exercises.—The commencement exercises of the Los Angeles Department of the College of Medicine of the University of California were held June 2, when a class of nine received degrees.——The fourteenth annual commencement exercises of the College of Physicians and Surgeons, San Francisco, were held May 19. The degree of doctor of medicine was conferred on a class of seven, and Dr. George Childs McDonald delivered the valedictory address, and the address to the graduates was made by Alden Anderson.

Testimonials to Professors.—A testimonal dinner was given in Los Angeles, June 2, in honor of Drs. Joseph Kurtz and George W. Lasher, who, after twenty-five years' service, are about to retire from the faculty of the Los Angeles Department of the College of Medicine of the University of California. A solid gold watch fob was presented to each from the faculty, alumni and students, by Dr. Edmond M. Lazard. Each of the guests was presented by Dr. John C. Ferbert with a handsome engraved set of resolutions, signed by each of the two hundred practitioners present.

Personal.—Dr. John E. Rodley, Chico, was thrown from his automobile, June 3, and seriously cut and bruised.——Dr. W. F. Lynch, Oakland, was stricken with paralysis in his office, May 21.——Dr. Charles A. Dukes, Oakland, has undertaken the duties of surgeon-general of California during the absence of Surgeon-General Winslow Anderson in Europe.——Dr. John C. King, Banning, who has been critically ill, is reported to be improving.——Dr. Clarence D. Dickey, San Bernardino, suffered a cerebral hemorrhage, May 8, while visiting in Los Angeles.——Dr. David B. Fields, Weaverville, has been reappointed physician of Trinity County.

COLORADO

Dinner for Medical Men.—Dr. Kate Lindsay, Boulder, president of the Colorado Woman's State Medical Society, entertained eighteen members of the organization at a dinner at the Boulder Sanatorium, June 1.

Personal.—Dr. Lewis Lemen and family and Dr. Seymour D. Van Meter, Denver, are in Europe.——Dr. Laura L. Liebhardt, Denver, has started for the other side.—Dr. William T. H. Baker, Pueblo, has resigned as assistant chief surgeon of the Colorado Fuel and Iron Company and will practice in Pueblo.——Dr. L. J. Beebee, Georgetown, has been made surgeon for the Colorado Southern Railway for the Georgetown District.——Dr. Addison C. McCain, Ault, is reported to be critically ill at St. Luke's Hospital, Denver, with appendicitis.——Dr. William A. Packard, Lamar, is suffering from a Colles' fracture, received while cranking his automobile.

ILLINOIS

Personal.—Dr. George A. Dicus, Streator, was operated on June 9, for appendicitis.——Dr. Vaclav H. Podstata, former superintendent of the Elgin State Hospital, has returned from a European trip.——Dr. Robert J. Burns, Freeport, has been appointed county physician.——Dr. Ralph M. Carter, Chicago, has been appointed on the medical staff of the Hinton Hospital, Hinton, W. Va.——Dr. John R. Sutter, Jr., Edwardsville, has been appointed county physician.——Dr. Daniel F. Duggan, Alton, has been appointed township physician.

Chicago

Alumnae Meet.—The Alumnae Association of the Northwestern University Woman's Medical School held its annual meeting, June 14. The following officers were elected: President, Dr. Eliza H. Root; vice-presidents, Drs. Annette S. Mack and Nora Soule Davenport; secretary, Dr. Anna Ross Lapham; treasurer, Dr. Mary C. Hollister, and trustees, Drs. Rachel Hickey Carr, Rose Willard, and Louise Acres.

Rush Class Reunion.—The class of 1899 of Rush Medical College held its annual reunion and dinner at the Bismarck Garden on the night of June 16. Covers were laid for fifteen. The following officers were elected for the ensuing year: President, Dr. William D. Byrne, Chicago; vice-president, Dr. Thomas R. Thomas, Lima, Ohio; secretary-treasurer, Dr. John B. Ellis, Chicago; and historian, Dr. Benjamin H. Breakstone, Chicago.

Program for Fourth of July.—To give organized expression to the growing public sentiment in favor of a "safe and sane Fourth of July," to aid in the enforcement of all laws designed to prevent the disorder accidents and fires attending the celebration of Independence Day, and to endeavor to secure such type of celebration as shall promote true patriotism, the Chicago Sane Fourth Association has arranged for a patriotic celebration of that day in the form of a parade and a military tournament under the direction of the Commanding General of the Department of the Lakes of the United States Army. The parade will be a grand pageant in three divisions, the first representing the United States of America, with various emblematic floats and five thousand United States troops representing all branches of the service, the second representing the state of Illinois, with the governor and the military organizations representing various wars of the republic, followed by floats and representations of historic events, and the third division representing Chicago, with the mayor, his cabinet and the city council, together with floats and paraphernalia representing the history and progress of the city, labor unions and other organizations, and a parade of the different nationalities represented in the city. The military display by the United States troops is a part of a great military tournament beginning on the Fourth of July and lasting ten days, in which there will be exhibitions displaying every phase of the soldier's life and duties, with sham battles, cavalry charges, and all the movements, evolutions and methods employed in training the soldiers for actual war. A great arena with seats for thousands is now being constructed and many troops are now preparing Grant Park for the great spectacle. This year's celebration promises to be a great beginning of the new way of celebrating Independence Day and will be an example to be followed by this and other cities in future.

KANSAS

Personal.—Dr. Charles M. Fullenwider, El Dorado, has returned from Europe.——Dr. Herbert G. Atkins, Kansas City, Mo., formerly intern in the German Hospital, has located in Pratt.

Commencement.—The twentieth anniversary of the Kansas Medical College, Medical Department of Washburn College, was celebrated June 3. Dr. Elmore S. Pettyjohn, Topeka, and Dr. John B. Tower, dean of the medical school, delivered addresses, and a class of fourteen received diplomas.

MARYLAND

State Health Board Appointments.—The State Board of Health, June 16, appointed the following officers under the new law: Dr. W. Franklin Hines, head of department of vital statistics; Dr. Wm. Royal Stokes, head of bacteriologic department; Dr. Caleb W. G. Rohrer, assistant chief of bureau of communicable diseases.——Dr. Charles Caspari, commissioner of pure food and drugs, assumed his duties on the same date.——The State Pharmaceutical Association has taken action to have a pharmacist on the State Board of Health. At present the board consists of five physicians, one engineer and the attorney-general. The Association thinks it more equitable that there should be four physicians and one pharmacist.

Baltimore

Personal.—Dr. Wm. Benjamin Dudley and Dr. Thomas R. Brown sailed for a tour of Europe.

Fellowships Conferred.—Johns Hopkins University has conferred the fellowship in pathology on Henry G. Barbour of Hartford, Conn., and the fellowship in psychology on John L. Ulrich, Baltimore.

Prominent Physician Injured.—Dr. George W. Dobbin, professor of obstetrics at the College of Physicans and Surgeons, was severely injured in an automobile collision on Thursday, June 2. He was taken to Mercy (city) Hospital where he was found to have a fractured skull and collar bone.

Johns Hopkins Commencement.—There were 64 medical graduates at the Johns Hopkins University thirty-fourth annual commencement June 14. Count Johann Heinrich von Bernsdorff, German Ambassdor to the United States, was the orator, his subject being: "The Development of the German Empire." Mr. Charles Chauncey Winsor Judd received the Lister prize of $150 for the best essay on "The Life and Work of Lister." Mr. Norman Harris Williams received the Joseph Kernochan Garr scholarship ($100) medical.

Reorganization of Supervisors of City Charities.—Dr. J. Hall Pleasants, president of the Board of Supervisors of City Charities, advocates the reorganization of medical supervision at the city hospital, Bayview. He proposes, independently of the medical schools, to get the best men for the positions. At present there is no right of selection. The Board of Estimates has endorsed Dr. Pleasants' proposition and authorized a change, to become effective on the completion of the new hospital. After January 1, the medical staff of the city hospital will consist of physician-in-chief, surgeon-in-chief, physician-in-charge of the tuberculosis hospital, physician in charge of the insane hospital, pathologist, and necessary associates and resident house officers. The five chief physicians, together with the superintendent of Bayview, will constitute the medical board of the city hospital, which is responsible to the city through the Board of Supervisors of City Charities. The medical board will be responsible for the discipline of the medical house officers, and each year will nominate the requisite number of candidates for appointments, to be selected after competition, to which graduates of any recognized medical school are eligible.

Hospital Changes.—Dr. Charles Bagley, Jr., superintendent of the Hebrew Hospital for the last four years, has resigned that position and will enter on private practice in Baltimore. He has been succeeded by Dr. Grover C. Ney, who has been the assistant physician for the last two years.——The Woman's Medical College of Baltimore, which closed its doors with the twenty-eighth annual commencement, held May 30, was founded with the hope that it would enlist the interest of many persons of means in this community who were interested in the professional education of women and would contribute to its endowment. They were destined to disappointment and the failure to secure endowment is responsible for the closing of the college. There was a movement here of Miss Garrett and her friends that promised well at one time, but it veered off to the Hopkins and was thus lost. This college was the first in Maryland to adopt preliminary and written examinations, a lengthened term, a three-year course, laboratory instruction, etc. Its standards were higher than most of the colleges in the country and it did a good work notwithstanding its small means. It was one of the founders and most ardent advocates of the American Medical College Association. It has had 116 graduates, of whom 30 have married and 90 per cent. are still in active practice. The remaining students will go next year to the Philadelphia school. The graduates of 1910 will mostly enter hospitals in the same city.——At the Baltimore Medical College the following changes are announced: Dr. Tilghman B. Marders becomes professor of biology, Dr. H. R. Kreider professor of chemistry, Dr. H. Raymond Spencer demonstrator of physiology, Dr. Reginald D. West demonstrator of anatomy. Dr. Edward L. Whitney has been reelected to the chair of physiological chemistry and pharmacology. The new members of the staff of the Maryland General Hospital, attached to the college, are: Drs. H. H. Cornforth, W. T. LaFortune, E. L. Bransford, H. F. Smith, J. J. Koarsak, D. Shack, P. Showalter and W. I. Neller.

MASSACHUSETTS

Grenfel Sails North.—Dr. W. L. Grenfel sailed from Boston, May 26, with a cargo of supplies for the north, including furniture for the new hospital in Labrador.

Catholic Physicians Found Guild.—About one hundred physicians met at the call of the archbishop in the conference room of the Cathedral of the Holy Cross, May 14, and organized St. Luke's Guild. The object of the guild is to oppose paganism of the times, combat the arrogant claims of physical scientists and schools of materialism, idealism and Eddyism.

Graduates.—At the thirty-first annual commencement exercises of the College of Physicians and Surgeons, Boston, June 1, a class of thirty-three was graduated. Addresses were delivered by Drs. John H. Kellogg, Battle Creek, Mich., on "The Possibilities of Preventive Medicine," and by Rev. J. H. Crooker on "The Doctor's Outlook on Life." The degrees were conferred by Hon. Joseph Bennett, president of the college.

Tuberculosis Board.—The governor has appointed the following members of a commission to investigate and report on the care of tuberculosis patients by state and local authorities: Dr. Henry P. Walcott, Cambridge, chairman; Dr. Julian A. Mead, Watertown, and Charles H. Porter, Quincy, from the State Board of Health; A. C. Ratshesky and Ada Eliot, Sheffield, from the State Board of Charities, and Dr. Arthur T. Cabot, Boston, and George A. Dunn, Gardner, from the commission on consumptive hospitals.

Personal.—Dr. Samuel Crowell, Boston, has been appointed a member of the Valley Forge Memorial Commission.——The house of Dr. George E. MacArthur, Ipswich, was damaged by fire to the extent of $2500, June 6.——Ward physicians of Lawrence have been reelected by the overseers of the poor with the exception of Dr. Patrick J. Hughes, who succeeded Dr. Emile E. Cyr for ward six.——Dr. Frank A. Woods, Holyoke, has been appointed a member of the Board of Pension Examiners for Hampden and Hampshire county, Vice Dr. Arthur B. Wetherell, resigned.——Dr. Joseph O. Beauchamp, Chicopee Falls, has been appointed a member of the license commission.——*Jerôme B. Greene, secretary of the Harvard* College Corporation, has resigned to accept the appointment of business manager of the Rockefeller Institute for Medical Research in New York City.——Dr. Harvey W. Cushing, formerly of Baltimore, has been appointed [illegible] the Peter Bent Brigham Hospital, Bostor [illegible] A. Christian, Boston, physician-in-chief.—Dr. Walter R. Brinckerhoff, who five years ago accepted a government appointment to make a bacteriologic study of leprosy at the lepper settlement in Molokai, H. I., has returned to the United States and has accepted a position as assistant professor of pathology in Harvard Medical School.

District Societies Meet.—The annual meeting of Worcester District Medical Society was held at Quinsigamond, May 11, and the following officers were elected: President, Dr. Albert C. Getchell, Worcester; vice-president, Dr. Charles A. Church, Millbury; secretary, Dr. Roy J. Ward, Worcester; treasurer, Dr. George O. Ward, Worcester; orator, Dr. John T. Duggan, Worcester; councilors, Drs. George E. Francis, Oliver H. Everett, Samuel B. Woodward, John T. Duggan, David Harrower, Homer Gage, Ray W. Greene, and Lemuel F. Woodward, Worcester; Edwin B. Harvey, Westboro; Ephraim W. Norwood, Spencer; Walter P. Bowers, Clinton, and Dr. William G. Reed, Southbridge; nominating councilor, Dr. Samuel B. Woodward, Worcester; censors, Drs. Ray W. Greene, Royal E. Watkins, and William J. Delehanty, Worcester, and Dr. Albert G. Hurd, Millbury, and Dr. James J. Goodwin, Clinton.——The one hundred and fifth annual meeting of Essex South District Medical Society was held in Salem, May 17, and the following officers elected: President, Dr. George H. Gray, Lynn; vice-president, Dr. George A. Stickney, Beverly; secretary, Dr. Walter G. Phippen, Salem; treasurer, Dr. George Z. Goodell, Salem; librarian, Dr. Carolus M. Cobb, Lynn, and councilors, Drs. Horace K. Foster, Peabody; Harry C. Boutelle, Danvers; Ralph E. Bicknell, Swampscott; Herbert J. Hall, Marblehead; Alfred T. Hawes, Lynn; William E. Tucker, Ipswich; Philip P. Moore, Gloucester; Edwin D. Towle, Salem; Augustine M. Tupper, Rockport, and John J. Hickey, Peabody; nominating councilor, Dr. Herbert J. Hall, Marblehead; alternate, Dr. Alfred T. Hawes, Lynn, and censors, Dr. Ara N. Sargent (supervisor) Salem, and Drs. Harry E. Sears, Beverly; George C. Parcher, Saugus; Philip P. Moore, Gloucester, and Frederick W. Baldwin, Danvers.——Hampshire District Medical Society met in Springfield, May 12, and elected the following officers: President, Dr. Bennis M. Ryan, Ware; vice-president, Dr. Nelson C. Haskell, Amherst; secretary, Dr. Arthur G. Minshall, Northampton; treasurer, Dr. Justus G. Hanson, Northampton; librarian, Dr. Frances L. Burnett, Northampton; censor, Dr. John S. Hitchcock, Northampton, and councilors, Drs. Frank H. Smith, Hadley; John S. Hitchcock, Northampton, and Edward D. Williams, East Hampton.

MISSISSIPPI

Degrees Conferred.—The first annual commencement exercises of the Medical Department of the University of Mississippi, Vicksburg, were held May 20. Dr. Hugh H. Haralson presided in the absence of the dean. The commencement address was delivered by Rev. William Mercer Green, and degrees were conferred on a class of four by Chancellor A. A. Kincannon of the university.

Society Meetings.—Clarksdale and Six Counties Medical Society, at its annual meeting in Clarksdale, elected the following officers: President, Dr. Robert L. Mercer, Shelby; secretary, Dr. Lewis E. Pierce, Stovall; and treasurer, Dr. Luther D. Harrison, Clarksdale.——Physicians representing Lowndes, Clay and Oktibbeha counties met in Columbus recently and discussed the organization of a tri-county medical society. Dr. Walter R. McKinley, Columbus, presided.

NEW YORK

Improvements at Columbus Hospital.—At the second anniversary of Columbus Hospital, Buffalo, Dr. Charles R. Borzilleri announced that plans were being prepared for the enlargement of the hospital to twice its present size. He also announced the following staff of the hospital: Consulting staff, internal medicine, Dr. Henry C. Buswell; surgery, Dr. Marshall Clinton; gynecology, Dr. Earl P. Lothrop; nose and throat, Drs. Max Keiser and James J. Mooney; nervous diseases, Dr. James W. Putman; ophthalmology, Dr. F. Park Lewis; orthopedics, Dr. Bernard Bartow; obstetrician, Dr. Peter W. Van Peyma; genito-urinary disease, Dr. Nelson W. Wilson; pediatrics, Dr. Irving M. Snow; dermatology, Dr. Grover W. Wende; pathology, Dr. Norman K. MacLeod, and radiographer, Dr. Alfred W. Bayliss. Attending staff: Internal medicine, Drs. Thomas J. Walsh, Horace LoGrasso and A. J. Getola; surgery and gynecology, Drs. Charles R. Borzilleri, Charles Battaglia and Edward E. Haley; nose and throat, Dr. Gianfrancisco; nervous diseases, Dr. F. Strozzi; orthopedics, Dr. Prescott LeBreton; obstetrics, Dr. L. Franklin Anderson; genito-urinary, Dr. Joseph J. Giambrone; pediatrics, Drs. John A. Ragone and Jacob W. Bayliss; dermatology, Dr. Grover W. Wende; pathology, Dr. Frank A. Valanti; anesthetist, Dr. L. Franklin Anderson; dental surgery, Dr. J. Panzica.

New York City

Personals.—Dr. and Mrs. Hermann M. Biggs, Dr. Edward B. Dench, Dr. C. Stafford McLean, Dr. H. Holbrook Curtis, Dr. and Mrs. Dwight W. Hunter, New York, have sailed for Europe.——Dr. and Mrs. Lucien L. Brainard, Little Falls, and Dr. and Mrs. William P. Faust, Schnectady, have also sailed. Dr. and Mrs. Richard Van Santvoord, New York, sailed on Saturday, June 18.

Fordham University to Build.—At the commencement exercises of Fordham University, Dr. James J. Walsh, dean of the medical faculty, announced that a new building for the medical department would be erected and ready for occupancy by next fall. The new building will be on the university grounds facing Pelham avenue. It is also planned to conduct a free clinic at the hospital. In the fall new schools of dentistry and pharmacy will be begun. Six students received the degree of M.D.

Commencement Exercises.—At the fifty-first annual commencement of the Long Island College Hospital, Brooklyn, June 1, a class of 68 was graduated. Dr. Joseph H. Raymond presented the candidates for graduation. Dr. John D. Rushmore, dean of the college, administered the Hippocratic oath, and Dr. John A. McCorkle presented the diplomas to the class. The twelfth annual commencement exercises of Cornell University Medical College were held at the college on Twenty-eighth Street and First Avenue, June 15.

Cornell University Confers Degrees.—The Cornell University Medical College graduated 68 students, seven of whom were women. President Jacob Gould Schurman addressed the graduating class on "Progress in Medical Education." He deplored the condition of medical education in the United States and emphasized the necessity of having hospitals under control of medical colleges. The best way to establish medical colleges and medical research on a higher plane was for the best hospitals to offer positions on their staffs to the professors in the best medical schools.

Society Opposes Losing Funds.—The Medical Society of the County of New York has issued a circular to its members urging each to write at once to the governor and mayor expressing his opposition to the bill which changes the existing medical law by adding at the end of the section, "Provided, however, that in the City of New York no fines shall be paid to any such societies, but shall belong to the said City of New York." Under the existing statute the medical society of the county receives the fines imposed on violators of the medical law whenever such violators are successfully prosecuted by the medical society.

Children's Hospital Alumni Organized.—At a meeting held May 26, the Association of the Alumni of St. John's Guild Hospitals for Children was organized with the object of maintenance of interest in the work of the hospitals in the guild, the consideration and discussion of matters pertaining to hygiene and diseases of infants and children, and for the promotion of friendly relations. The following officers were elected: President, Dr. Medwin Leale; vice-president, Dr. Russell Bayly; secretary, Dr. Carlisle S. Boyd; treasurer, Dr. William Ten Eyck Elmendorf; executive committee, the officers and Drs. W. Morgan Hartshorn, Harry D. Johnson and Phillip Smith.

OHIO

A Test of the Vital Statistics Law.—Dr. J. J. Boone, a physician residing in Hardin county, after repeated violations of the vital statistics law in refusing to report births, was convicted in the common pleas court of that county. It is stated that, in taking the case up to the supreme court of the state, he solicited financial aid from a number of county societies belonging to the state organization, and received such aid from one or two. The House of Delegates of the Ohio State Medical Society, at its meeting in May, passed a resolution to the effect that no component society of the state organization could consistently give aid in the defense of any member violating the provisions of the vital statistics law of the state.

PENNSYLVANIA

Franklin County's Roster.—The Quarterly Call and Roster of the Franklin County Medical Society will be enlarged. It is one of the many manifestations of activities shown by the various county medical societies throughout the state, in the contest for medical organization for the material betterment of practitioners.

Philadelphia

Organized Labor and Tuberculosis.—At a meeting held at the Central Labor Union's headquarters, J. Byron Deacon, executive secretary of the Pennsylvania Society for the Prevention of Tuberculosis, asserted that the society was prepared to offer organized labor the use of 100 beds for tuberculosis patients, at a cost per capita of 20 cents per year. The society would do this until such time as organized labor could erect its own sanatorium. This offer was made following the report of a committee of eleven, appointed by the union at a previous meeting, for the purpose of cooperating with the Pennsylvania Society.

University of Pennsylvania Commencement.—The one hundred and fifty-fourth annual commencement was held at the Academy of Music on June 15. Secretary of State Philander C. Knox, delivered the annual address, taking for his subject, "The Spirit and Purpose of American Diplomacy." A sum of $10,000 has been raised by the four classes of the university to defray the cost of the erection of a life size bronze statue of Provost Charles C. Harrison. The statue will be placed at Thirty-sixth and Locust streets. The standard flag of the college, which is red and blue, was modified by the addition of the seal of William Penn in the center.

Personal.—Surgeon-General George H. Torney of the United States Army, Surgeon-General Charles F. Stokes of the United States Navy, and the medical officers of the Army and Navy stationed at Philadelphia were the guests of the Medical Club at a reception held at Bellevue Stratford, June 17.——Dr. A. M. Richards of Northwestern University was elected professor of pharmacology at the University of Pennsylvania, and Dr. K. F. Meyer of the Transvaal, Africa, was elected assistant professor of veterinary pathology.——Dr. Louis A. Duhring, professor of dermatology, resigned from the University Staff on account of ill health.——Dr. and Mrs. Louis Somers have sailed for Europe on a two months' trip.

WISCONSIN

Marquette Medical Graduates.—The Medical Department of Marquette University held its graduation exercises, May 23. A class of forty-five was graduated.

Personal.—Dr. Mazyck P. Ravenel, Madison, has been appointed to represent the University of Wisconsin at the centennial celebration of the University of Berlin, October 10 to 13. He is also a delegate to the International Conference on Tuberculosis and the International Congress on Alimentary Hygiene and the Rational Feeding of Man which meets in Brussels.——The City Council of Milwaukee has confirmed the appointment of Dr. William Colby Rucker as health physician.——Dr. John M. Helgeson has been appointed health officer of Rice Lake.

GENERAL NEWS AND COMMENT

New Hospital.—A contract has been awarded to build a new reinforced concrete hospital at Fort McKinley, P. I. It is proposed to add one wing to the hospital each year until it finally develops into a hospital available for a brigade post. A double set of quarters for hospital stewards at Fort McKinley is also to be constructed.

Memorial Window Unveiled.—On May 8 an interesting service was held in the Hospital Church of St. Luke the Beloved Physician, Ancon, C. Z., when windows erected in memory of those who had lost their lives during the construction of the canal were unveiled by Col. William C. Gorgas, Medical Corps, U. S. Army, chief sanitary officer of the Isthmian Canal Commission.

Tuberculosis Sunday Results.—The National Association on Tuberculosis reports that on Tuberculosis Sunday 4,000,000 people listened to 40,000 sermons and that 1,250,000 pieces of literature were distributed; one-eighth of all the church goers of the United States heard the gospel of health on that Sunday. Plans are under way to make Tuberculosis Sunday work more far-reaching next year.

Library Wants Sanitary Reports.—The New York Academy of Medicine is desirous of adding to its library the reports of the committees that have been appointed from time to time to investigate questions of public health, to the end that the results of their labors may be available to future workers. Among the topics on which information is desired are: Harbor pollution, the alcohol question, the prevention of tuberculosis, the prevention of occupational diseases, the sanitation of tenements and work-shops, the effects of prolonged hours of labor, the social evil and congestion of population. The Academy will be glad to receive copies of reports of this nature and also any information concerning the appointment, the name and work of committees or commissions engaged in this research. Communications may be addressed to Dr. Charles Mallory Williams, Executive Librarian, New York Academy of Medicine, 17 W. Forty-third Street.

Federation for Sex-Hygiene.—The American Federation for Sex-Hygiene was organized at St. Louis, June 6, by delegates from fifteen state and city organizations interested in the promotion of the education in sex matters. The following officers were elected: Honorary president, Dr. Charles W. Eliot, formerly president of Harvard University; president, Dr. Prince A. Morrow, New York City; vice-presidents, Rev. George R. Dodson, D.D., St. Louis, Prof. Charles R. Henderson, Chicago, Talcott Williams, Philadelphia, and Dr. Francis Green, California; executive committee, Drs. Robert N. Willson, Philadelphia, Donald R. Hooker, Baltimore, William F. Snow, Stanford University, Thomas N. Hepburn, Hartford, Edward Jackson, Denver, and Malone Duggan, San Antonio, Tex.; and Messrs. Wert W. Hallam, Chicago, Percy Warner, St. Louis, and Delavan King, Boston.

The purpose of the organization is "the education of the public in sex physiology and sex hygiene, and the study of every means, educational and sanitary, moral and legislative, for the prevention of certain sex diseases."

Visit of American Surgeons to England.—The following members of the American Society of Clinical Surgery sailed on the Mauretania Wednesday, June 22, for England; R. G. LeConte, G. G. Davis, J. P. Hutchinson, John Gibbon, C. H. Frazier, Edward Martin, *Philadelphia*; C. H. Peck, G. E. Brewer, J. A. Blake, *New York*; A. D. Bevan, L. L. McArthur, J. B. Murphy, M. L. Harris, Chicago; F. B. Lund, E. A. Codman, C. A. Porter, John C. Munro, Boston; Emmet Rixford, San Francisco; C. H. Mayo, Rochester, Minn.; G. W. Crile, Cleveland; Willard Bartlett, St. Louis, and J. M. T. Finney, Baltimore. The society will be entertained by the leading surgeons of England. The plan outlined is to spend ten days in the leading cities of England and Scotland, where a series of clinical demonstrations have been arranged by the leading surgeons of Great Britain. Among the social attentions to be tendered the surgeons are a visit to Oxford, where they will be entertained by Professor Osler, with a dinner at Christ church following, a cricket match at Lord's and a visit to the House of Commons. The tour is a unique one, but one that certainly will result, not only in bringing about a closer relationship between British and American surgeons, but also in an appreciation of the work that is being done that would not be possible under ordinary circumstances. Most of the party will return on the Lusitania, sailing from Liverpool July 9, although a few will extend their trip to the Continent.

Distribution of Anti-Meningitis Serum.—The Rockefeller Institute for Medical Research, which has been supplying the antimeningitis serum gratis for several years, has announced that it may discontinue, at any time after the expiration of the next six months, its preparation and distribution on a large scale. The consensus of medical opinion, based on the employment of the antimeningitis serum in widely separated epidemics of meningitis, is to the effect that it is of undoubted value in reducing the mortality and preventing the severe consequences of the disease. The serum is without effect in any other form of meningitis than that caused by diplococcus intracellularis (Weichselbaum) and its favorable action is most pronounced when it is applied early in the course of the disease. Hence it is desirable that state and municipal laboratories, engaged in the preparation of diphtheria antitoxin and allied products, should undertake the preparation of the serum and provide means for controlling the bacteriologic diagnosis of meningitis, as they now do diphtheria and some other diseases. Unless the bacteriological diagnosis is controlled by competent authorities, the serum will, undoubtedly, be applied in some cases of meningitis due to causes which are not subject to its action, and not a few cases of epidemic meningitis will be deprived of the benefits of its use. The serum is administered by being injected into the spinal canal by means of lumbar puncture, which operation is also required to secure the fluid for the bacteriological diagnosis; and several separate injections of the serum are required in treating a given case. The effective employment of the serum is likely, therefore, to be restricted on account of the experience and skill required in its administration and the high cost of the commercial product, unless the preparation, distribution and, when necessary, administration are undertaken by state and municipal authorities.

LONDON LETTER

(From Our Regular Correspondent)

London, June 4, 1910.

Physicians Oppose Even Moderate Use of Alcohol

The tendency of recent years has been to limit considerably the field of the utility of alcohol, and the amount consumed in the hospitals is a mere fraction of that consumed a few years ago. From time to time manifestos on the alcohol question signed by numerous and influential members of the medical profession have been published for the instruction of the public. They have generally been against the use of alcohol. A manifesto has just been issued by 101 doctors in North Wales, of whom 34 are health officers, to the following effect: "Recognizing the very serious injury to the national health caused by the present-day extensive over-indulgence in the various forms of alcoholic drink; recognizing also that the habit of over-indulgence is seldom if ever suddenly acquired, but grows gradually out of what is considered to be a moderate use, and generally in the belief that such moderate use promotes health, increases the power of work, prolongs life; convinced moreover that this belief is a dangerous delusion and one which prolonged observation and exact experiments of scientific men have conclusively proved to be so: We, the undersigned, appeal to all our medical brethren in North Wales to join us in an endeavor to discountenance the various popular errors that still largely prevail on this subject. We appeal to them especially not to give, or even seem to give, the sanction of their professional authority to any general employment of alcoholic drinks in cases of disease. We believe that these drinks are not necessary for the promotion of health; that they do not increase but on the contrary impair physical and mental efficiency, and that they do not prolong life."

Great Scheme for the Providing of Dental Aid

A philanthropist who desires to remain anonymous has placed at the disposal of a prominent official of the British Dental Association the sum of $1,000,000 on "philanthropy and 5 per cent." terms for the establishment of a national dental aid organization for the benefit of the lower middle and poorer classes of the community willing to pay small fees for dental treatment and appliances, but who are unable to pay ordinary fees—in short, for the establishment of dental hospitals for paying patients—a much-needed bridge over the gap between the dentist and the ordinary dental hospitals. The problem is an old one and has been under the consideration of the authorities for many years but hitherto has been insoluble owing to the difficulty of obtaining capital. Suggestions of State assistance have been put forward but the obvious objection arose that the class to be catered to are unwilling to be the subjects of State or other charity. At present the benefits of conservative dentistry are confined to the well-to-do and the very poor, who are treated free at the hospitals, while individuals in the large intermediate class are unable to obtain them. The need for some such scheme is shown by the deplorable condition of the teeth of people in Great Britain. The mouths of the English have become a by-word in Europe. From 70 to 90 per cent. of school children suffer from defective teeth and start life badly crippled and unfit for the public service. Sixty-four recruits for the army per 1,000 are rejected for bad teeth (11 in excess of the next most frequent cause—"under chest measurement") and nearly 3 per 1,000 are rejected after enlistment for the same cause. During the late South African War 3,000 men had to be sent home as unfit for active service in consequence of defective teeth, in spite of the presence of army dentists. Subject to acceptance of the offer, a start will be made at once by starting a clinic in London. If successful this will be followed by similar establishments in every important town. To secure success it will be necessary to obtain the cooperation of the medical and dental professions, and the active support of many societies working in the interests of national health and hygiene. Though the provision of a national dental service will be the main object, a second mission will be the teaching of prophylaxis by the employment of paid visitors and lecturers on the principles of dental hygiene.

The Dangers of Rag Flock

A government report just issued calls attention to a danger which has been discussed from time to time in the medical press without, however, the provision of any remedy. The substance known as rag flock which is used for the stuffing of the cheaper kinds of mattresses and upholstery is manufactured from all kinds of old rags. According to the report, the rags used are of the lowest grade and consist largely of cast-off clothing and strips of old carpet which may have been picked out from rubbish heaps. The rags are passed through a tearing machine termed a "devil." Although in this process much of the dirt is removed yet a large quantity remains. Dr. Farrar, one of the government inspectors, estimates that from 70 to 90 per cent. of the flock used for bedding and upholstery is neither washed nor sterilized, and the filthy nature of some of it is appalling. He states that old trousers often badly stained with urine and feces are among the commonest articles he has seen passed unwashed into the tearing machine. Some manufacturers purchase old beds and work up the contained flock, unwashed, with freshly torn material. Among other articles which are passed into the machine are surgical bandages and dressings, and stained towels. Another inspector, Mr. Warburton, reports that lice may pass through the machine without being crushed and though the adult animals would probably not survive any time in the bedding made from the flock their eggs would. Professor Nuttall and Dr. Graham-Smith have made pathologic experiments with flock and have by subcutaneous inoculation induced septicemia in mice. Dr. Farrar suggests that a standard of cleanliness for rag flock should be prescribed by law. He finds that there is no difficulty in discriminating between clean and dirty flock by chemical analysis. The average amount of chlorine in a liter of fluid prepared from washed flock he finds to be 6.5 milligrammes, and from unwashed flock 113 milligrammes. He suggests that 10 milligrammes of chlorin in one liter of wash prepared from the flock on regulated lines should be the permissible limit of impurity. Professor Nuttall and Dr. Graham-Smith agree that a bacteriologic standard is not feasible because the mere sterilization of flock would not remove the organic dirt.

Alcoholism and Offspring

The doctrine that alcoholism in parents is injurious to the offspring has been submitted to the test of investigation in the Francis Galton Laboratory for National Eugenics. The investigation has been conducted by Miss Ethel M. Elderton, Galton Research scholar in the University of London, assisted by Prof. Karl Pearson, F.R.S. More than 3,600 school children were examined and a comparison was made between those who had parents addicted to alcohol and those who had not. A higher death-rate was found among the children of alcoholic than among the children of sober parents. This was higher when the mother was alcoholic than when the father was. It appeared to be due considerably to accidents and gross carelessness of the parents. The mean weight and height of the children of alcoholic parents were found to be not inferior to those of the children of sober parents. The startling observation was made that the general health of the children of alcoholic parents was on the whole slightly better than that of the children of sober parents. There were fewer delicate children among the former and cases of tuberculosis and epilepsy were markedly fewer. The explanation given is as follows: The physically strongest in the community have probably the greatest capacity and taste for alcohol. Further, the higher death-rate of the children of alcoholic parents probably leaves the fitter to survive. Epilepsy and tuberculosis, depending on inherited constitutional conditions, will be more common in the parents of affected offspring and probably, if combined with alcohol, are incompatible with any length of life or size of family. Parental alcoholism was found not to be a source of mental defect in offspring. The relation, if any, between parental alcoholism and filial intelligence was so slight that no numerical value could be assigned to it.

PARIS LETTER

(From Our Regular Correspondent)

Paris, June 3, 1910.

Epidemic of Acute Poliomyelitis in Paris

During the session of May 31 of the Academy of Medicine, Dr. Netter, physician of the Trousseau Hospital at Paris, read a paper on the epidemic of poliomyelitis observed in Paris following the summer of 1909, and again in last January owing to peculiar climatic conditions at the beginning of the year. In comparing this epidemic with those of New York City in 1909, of Sweden in 1905, of Norway in 1906, etc., Dr. Netter emphasized especially the fact that great epidemics are usually preceded and followed by smaller epidemics and that epidemic outbreaks in various parts of the world coexist or very closely follow each other. Like cerebrospinal meningitis, poliomyelitis is sometimes very contagious, sometimes scarcely contagious at all. The mortality exceeds 10 per cent. Aided by Levaditi, Netter has been able to prove that serum of patients who have had infantile paralysis presents neutralizing properties toward the virus of poliomyelitis.

Election of Two National Correspondents to the Academy of Medicine

In its session of May 31 the Académie de Médecine elected as national correspondents Dr. Regis, adjunct professor in the clinic of mental diseases of the Bordeaux college of medicine, and Dr. Collignon of Cherbourg.

The First Assembly of French Hospital Interns

The first Congrès Français de l'Internat des Hôpitaux (mentioned in The Journal, March 5, 1910, liv, 804) opened May 12 at Bordeaux. The following resolution was adopted: "In view of the fact that the internship is universally considered an incomparable school of medical and surgical education of which foreign physicians are justly envious, this meeting adopts the unanimous resolution to defend the institution of the internship, obtained competitively, against all the measures which would tend to suppress or to diminish its prerogative."

As for the method of recruiting, the assembly resolved in favor of the mode at present in force, that is to say by *concours*, with the necessity of passing through the externship. The sense of the meeting was that foreign candidates may be admitted to compete for the externship and the internship, provided they furnish all the diplomas and other conditions required of French students.

As for the scientific organization of internship, the assembly adopted two resolutions, one in regard to the creation of laboratories for scientific research in the internship and the other to the effect that during their service interns should, at their request, be given leave for a year to make a journey for scientific study among the university cities and abroad, and that competitions should be held for purses of travel, either in France or abroad, the beneficiaries being under obligation to make a scientific report on a question decided in advance by them.

The second assembly of hospital interns will take place in Paris next year.

A New Regulation for the Sanitary Service of the Army in the Field

A new regulation for the sanitary service of the army in the field has just been prepared by a special commission, of which the medical inspectors-general Vaillard, Delorme, Claudet, and others, are members. This regulation is based on the following essential principles: (1) division of the regimental sanitary service into two parts, one of which is to follow the troops in action, while the other is to be stationed in the rear; (2) increase in the number and decrease in the weight of the ambulances, which are capable of being immobilized, or transformed into field hospitals by the addition of "sections d'hospitalisation;" (3) increase in the number of litter-bearers for the transportation of the wounded, under the command of physicians. Laws have previously made the sanitary service autonomous under the orders of the physicians; and according to these laws, everyone in the sanitary service was under the authority of the physicians. Physicians in the French army, however (unlike those in the German army, for instance), are not considered combatants although they have their designated place on the field of battle and in all wars many of them have been wounded by the enemy's fire. Not being combatants, their right to give orders and to exercise discipline over the members of the military transport service has been disputed. The new regulation grants to officers of the sanitary corps the necessary authority in this respect.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, June 1, 1910.

Details of the Death of Robert Koch

As you have already learned by telegraph, Robert Koch died May 27 at Baden-Baden. The apprehension which I already expressed in my first report of his illness many weeks ago was soon justified. A new attack of heart failure terminated his life. It goes without saying that one cannot adequately measure the importance of this gifted man in a letter and I may rightly assume that you will make a special tribute to the great master in your Journal. Surely in him we have lost one of the greatest physicians of the present time, indeed one may say without offense to anyone, the greatest, for no one has so impressed himself on the medicine of our time as Robert Koch. Since the present age of medicine may rightly be designated as the etiologic age, Robert Koch may be regarded as a creator of it. For while the foundation of modern bacteriology had already been laid by Pasteur and Lister, Robert Koch was the first to succeed by his investigations in securing a firm basis on which to build a system of infectious diseases in their etiologic relations. Inasmuch as his teachings also had secured the greatest results for public and social hygiene, the value of his lifework must receive a higher estimate than even that of a Rudolf Virchow. Sorrow at his death finds worthy expression in the entire civilized world as is shown by the dispatches. The two physicians who treated him, Professors Kraus and Brieger, of whom the latter, as is well known, is one of his most gifted pupils, make an extensive report in the *Deutsche medizinische Wochenschrift* regarding his last illness. In consideration of the interest that this clinical history possesses from a general scientific standpoint, I would like to give you an extensive abstract of it: Koch suffered from anginal symptoms since March, 1910, and for a year or more previous the pulse had been intermittent. The attacks which became steadily longer and severer, he overcame by his energy of will. Up to the last he worked daily from about 9 in the morning until 2 p. m. in the laboratory of the institute for infectious diseases and his ward in the Virchow hospital. Koch had for years considerable cough and occasional expectoration, but bacilli were never demonstrated. In the end of 1890 he passed through a severe left-sided pneumonia. During his tour in Japan, Africa and America he experienced no special difficulty.

Koch was never a heavy smoker nor addicted to the use of spiritous liquors, but he did not spare his body in any way during his travels and in his scientific work. He had once a severe attack of cholera and had repeatedly suffered from malaria and often had disturbances of the bowels. In the night of April 9, Koch without recognizable cause was attacked with heart failure of the severest kind. After a short sleep he awoke with a feeling of impending death, with heavy perspiration, severe dyspnea and vomiting. At the same time a sharp pain radiated from the precordium to the left shoulder. Immediately he noticed marked râles in the bronchi which were also evident to the bystanders. In this condition Brieger found him sitting on the edge of the bed with ice-cold extremities, in agonizing dyspnea, completely collapsed, but awaiting his end with a mind clear and composed. The pulse was thread-like with a frequency of about 80 (previously 58) and very irregular. An injection of morphin gave him relief after about fifteen minutes. He slept until 9 in the morning and then awoke with similar symptoms, specially the râles, the dyspnea and the heart weakness. Toward noon Brieger and Kraus examined Koch together. They found the condition better than in the night. The left ventricle of the heart was moderately hypertrophied. There was general edema of the lung with a frothy, serous and sanguinolent expectoration and a very frequent and irregular pulse. The heart tones were dull and faint. There was marked rigidity and contortion of all the palpable and visible arteries. The liver was slightly swollen, there was very slight increase of urine. It must be assumed that in consequence of disease of the coronary artery, a softening of the heart muscle had taken place. The next morning while the pain in the region of the heart had become especially severe a loud pericardial murmur could be heard. In addition there were marked hematuria and cylindruria. The temperature was somewhat raised one evening only. The friction sound disappeared after two days but a recognizable effusion of fluid did not occur. At the same time the urine regained its normal color, and was quite free from albumin and casts. At first the treatment consisted in the administration of digitalis, morphin and strong coffee, and the application of warm compresses to the region of the heart and to the feet and hands. Under this treatment a condition of comfort was secured which continued very satisfactorily for a week. The patient who at first had calculated that he would live three and later eight days acquired again a degree of courage, his appetite increased, the amount of urine rose to 1800 c.c. and the swelling of the liver was reduced. The pulse showed an average frequency of 60 and while the tension remained low the rhythm was good. The edema of the lung, however, was more obstinate and especially on the left side it continued and never fully disappeared. After the first week, the heart beat became for a few days unduly frequent, the pulse thin and very irregular and the edema increased. Treatment with digitalis also relieved this intermediate attack. After this the pulse rate was kept at 60, the tension of the pulse soon became much better and the blood pressure rose to 144 mm. Hg. The patient was able to be out of bed for days at a time. After May 14 he took several rides, received his friends and tried to read, to dictate and to carry on some literary work. Unfortunately the condition continued such that even with the moderate frequency of the pulse and a tolerable tension, the slightest emotion or light muscular effort, walking, etc., immediately produced marked acceleration of respiration.

A careful medical examination in the middle of May gave the following results: Arteriosclerosis, blood pressure 110-160 mm. Hg., normal rhythm (even with single ventricular extrasystoles), hypertrophy and dilatation of the left ventricle (as determined by the apex beat and the *x*-ray) enlargement of the left auricle. Murmurs in the heart were not again heard. The [illegible] showed a marked variation in the auricle [illegible]” was markedly negative. The glands at the root of the lung appeared to be markedly enlarged on both sides, the tracing of the hilus was abnormally sharp and the left lung was insufficiently clear in the lower section. In the region of the apices there were no shadows (*x*-ray). Koch stated finally that he had had an old tuberculosis but for the moment he was more easy with regard to his dyspnea, for he had no fear of tuberculosis.

Koch was a quiet, uncomplaining and obedient patient. He did everything that the physicians directed, observed himself with greatest interest, discussed the progress in the findings and preserved always a stoic tranquility. He was pleased as a child when with increasing appetite the porridge which he had become so fond of in England tasted good again. So soon as the conversation turned on scientific matters he forgot immediately all his suffering, his eye sparkled under his high brow and only his dyspnea reminded him of the limits assigned to his physical powers. The prognosis from the very beginning was unfortunately bad. The little improvement in the findings which made possible a life in the arm chair and short promenades in his room deceived no one. Koch very earnestly desired to escape from the confinement of his room to Baden-Baden, where his friend, Libbertz, was staying. He stood the journey very well at which he was very much pleased. May 27 an aggravation of the condition suddenly occurred, and after an attack lasting for a few moments, death followed. Following his directions the body was cremated at Baden-Baden. According to his wish flowers were omitted and the funeral was strictly private. With reference to memorial services which are to be held at Berlin no definite arrangement has yet been made.

Personal

Professor Hess, of Würzburg, has been called to Heidelberg as successor of Professor Leber in the chair of ophthalmology. Professor von Krehl is proposed as a successor of Curschmann. Whether Krehl, who is almost always called as successor when a chair for internal medicine is vacant in one of the German universities, will accept this call seems doubtful. He refused the proposal to become successor of v. Leyden, but possibly the chance to secure the position which his teacher formerly occupied may prove attractive to him.

International Union Against Tuberculosis

On May 22 the managing committee of the international association against tuberculosis held its meeting here under the presidency of the head of the imperial health office. Besides Germany there were represented Austria, England, France, Sweden, Holland, and Denmark. The discussions were on the lines on which the international tuberculosis conferences in Brussels and Rome shall be organized; also the participation in the international exposition that is to take place in Dresden was taken under consideration. Further, the suggestion was made to communicate the results of investigation of consumptives in the form of a set of uniform signs and abbreviations, and thus to facilitate the mutual understanding between the different civilized nations. Also, the question of international tuberculosis statistics is to be further investigated.

Discussion of Limitation of the Privileges Granted Foreign Students in the German Universities

Frequent complaint has been made of late years in the press that in consequence of the large ingress of foreign students, the native students at our universities and technical schools are deprived of the best places, and it has been urgently recommended that the excess of foreigners should be restricted. This subject was discussed a short time ago in the Prussian parliament. In this discussion the inconveniences that our native students suffer from the presence of foreigners, as well as the great value which the attendance at our universities possesses for foreign students, were thoroughly recognized. The Prussian minister of education expressed his opinion on this question, and it is well worth while for you and all those who desire to visit Germany for the purpose of study to learn the exact wording of the remarks which the minister made: "The Prussian universities have constantly regarded it as an agreeable duty imposed on them to assure hospitality to foreigners and to open to them as well as to our own youths the public lecture halls, so that they may draw from the wells of knowledge, learn German science, and return to their fatherland with the knowledge and impressions which they have acquired, where they have often become steady, true and valuable friends to us. To this policy we will still adhere, as it corresponds to the ancient tradition and to the high position which our universities, even today, still hold in the world." It is true that the minister added that in the case of institutions which demand considerable expense on the part of the state and where the question of room plays so great a rôle that it is possible to accommodate only a limited circle of hearers, it is probable that an increase of the fees for foreigners would be justified. This question will be investigated further by the department. In this matter a distinguished member of the parliament made the suggestion that an exchange of students might be arranged, similar to that which exists between the professors, and the desire was expressed especially that for German students who are studying in American universities the time that has been spent in Germany, and especially in Prussia, should be reckoned in the time required for attendance. The minister will give effect to this wish.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, June 3, 1910.

Death of Professor Zuckerkandl

One of the most famous medical men of the old Vienna school passed away a few days ago in the person of Prof. Emil Zuckerkandl, the well-known anatomist, whose loss is felt keenly by his numerous friends and pupils. Zuckerkandl's name is known all over the world in connection with his researches on the anatomy of the nose and its accessory sinuses, as well as his work on the anatomy of the brain, the nervous system and topography of the human body. He continued the important investigations of his teacher, Hyrtl, on the circulatory system of the vertebrate animals. Nearly all the practitioners of the present generation were his pupils, and his animated style of lecturing with digressions on artistic motives in anatomy, as well as his splendid teaching qualities, caused students to throng his classes. A special feature in his method of teaching was the intimate personal contact with his students in the dissecting-room, where he spent all his free time teaching, demonstrating, investigating and explaining. Zuckerkandl's career was very brilliant. Born in 1849 he soon turned to medicine, and Hyrtl, then the leading anatomist, at once recognized the qualities of a scientist in the young student. Five years after graduation (1879) he was appointed extraordinary professor of anatomy in Vienna, after having been privat-docent in Utrecht, Holland, for a couple of years. In 1888, after having filled the post of ordinary professor in Graz, he was asked to succeed Karl Langer in Vienna, and thereafter he maintained the high position of the Vienna school which his predecessors had founded. The enumeration of his papers and publications is unnecessary here. It is sufficient to note that he was the recognized leader of anatomy in Central Europe.

Postgraduate Instruction for Army Physicians in the Vienna Hospitals

The institution of postgraduate classes for practitioners has received the universal approval of all medical circles, and it has been resolved to make it a permanent feature of the teaching in our hospitals. The military authorities have also availed themselves of the opportunity thus offered to them by sending the medical officers of the home and the territorial force in turns to the postgraduate classes. Every military physician who has served at least 3 years is entitled to apply for 6 months' to 12 months' leave for the purpose of attending these classes. He is paid his full salary and the fees for the classes are paid for him by the government. He must satisfy the army board that he has profited by the teaching. He has to stay at least three months in one of the wards, taking his turn three or four times in different stations. For each year spent thus in hospital he has to remain at least 18 months longer in the army than the minimum time (6 years). These classes offer an excellent opportunity for the army physicians, and they flock to the hospitals. Surgery, ophthalmology, urology and rhino-otology especially are favored by them, while classes on bacteriology and sanitation, which are of such paramount importance for the army surgeon, are always crowded with these men. The facilities for learning are great, and the advantage of better promotion, increased knowledge and better pay are great inducements. Thus, in 1909, more than 260 regimental surgeons were enrolled in these classes.

Correspondence

The Layman's Reply to the Medical Freedom (?) League

The following is a copy of a letter sent to the leading newspapers of the country by Prof. Irving Fisher, president of the Committee of One Hundred on National Health. It will be interesting to see how many newspapers publish it:

To the Editor: Buying newspaper space appears to be the latest method of opposing a popular movement. Within a few weeks, three enormous advertisements, by a so-called "League for Medical Freedom," have appeared in newspapers throughout the country urging people to write their congressmen in protest against the Owen bill for a national department of health. Much to the amusement of congressmen, these advertisements have resulted in numerous telegrams, based on the absurd idea that the Owen bill aims to regulate the practice of medicine.

The result may be to aid, rather than hinder, the progress of the health movement. Already newspaper editorials—such as that which recently appeared in the *New York Times*—resent the buncombe of these advertisements.

But besides adding to the "gaiety of nations," this incident has created an appetite among the general public for more knowledge as to what this opposition signifies.

As president of the Committee of One Hundred on National Health, which was challenged in these advertisements, I wish to emphasize the following facts:

First: As the enclosed bulletin of the Committee of One Hundred indicates, the real strength of the opposition evidently comes from commercial interests, such as the quack medicine interests and others who have reason to fear the Food and Drugs Act. While Christian Scientists and other "drugless" cults are denouncing drug doctors and denouncing a "medical trust" which does not exist, these cults are themselves playing into the hands of a drug trust which does exist.

Second: Under our Constitution, the federal government could not, if it would, regulate the practice of medicine.

Third: The Owen bill contains no provisions aiming to regulate the practice of medicine.

Fourth: Section 8, in the Owen bill, the section authorizing the establishment of "chemical, biologic and other standards," has been eliminated entirely from the bill, although only a heated imagination could have construed this section as attempting to regulate the practice of medicine.

Fifth: Senator Owen did not prepare his bill at the instance either of the American Medical Association or of the Committee of One Hundred on National Health. It is true, however, that the American Medical Association and the Committee of One Hundred heartily endorse the bill in preference to any of the other numerous health bills now before Congress.

Sixth: The Committee of One Hundred on National Health is not a medical organization. It did not originate with the American Medical Association, but with the American Association for the Advancement of Science. It is allied with the American Medical Association only in the same sense that it is allied with labor organizations, farmer organizations, life insurance companies and various other agencies which are working to improve public health.

Seventh: While opposed to fraudulent quackery, which is always imposing "fake" medicines and cure-alls on the public, the Committee of One Hundred on National Health is not devoted to any particular school of medicine to the exclusion of others. Curiously enough, it was a Christian Scientist who moved the appointment of the Committee of One Hundred. Many members of our committee have been noted for their independence of conventional medicine, among them being ex-President Eliot of Harvard University; Mr. William H. Allen; Mr. Edwin Bok, editor of the *Ladies' Home Journal;* Mr. Horace Fletcher, Dr. Luther H. Gulick, President G. Stanley Hall, Mrs. John B. Henderson, Dr. J. H. Kellogg, Mr. S. S. McClure of *McClure's Magazine;* Dr. Richard C. Newton, who has called attention to some merits of osteopathy; and Mr. Nathan Straus. I may add that in my report on "National Vitality" to President Roosevelt, I put myself on record as favoring "medical freedom." I can endorse almost all of the position on that subject taken by Mr. Fowler.

Eighth: A department of health in America like the department of health in Germany, or anywhere else, will have better things to do than to regulate the practice of medicine. It will regulate the misbranding of foods and drugs (there's the rub!), the pollution of streams, the inspection of meats and quarantine and will obtain and distribute information in regard to health of human beings just as the Department of Agriculture does in regard to the health of hogs and cattle.

When the "League for Medical Freedom" suddenly appeared on the horizon, our movement had encountered substantially no opposition except among quacks and quack medicine proprietors. On the other hand, our movement has the support of the President, of both political parties, as expressed in their platforms, of scientific, philanthropic, medical and labor organizations and of the granges, as well as of the life-insurance companies, of Dr. H. W. Wiley of the Bureau of Chemistry and of General Walter Wyman of the Public Health and Marine-Hospital Service. The general public will find it hard to believe that these endorsements, especially the hearty endorsement of the life-insurance companies, can be in the interests of a "medical trust."

For further information, I would refer the reader to Bulletin 41 of the Committee of One Hundred about to be issued (address Drawer 45, New Haven, Conn.) to the Senate reports (Nos. 1 and 2) on hearings on S. 6049 (address Senate document room) to House reports of hearings on health bills, June 2-6 (address document room, House of Representatives) to Senator Owen's speeches (address Senator Owen) and to my report on National Vitality (Senate document 419).

Irving Fisher, President.
Committee of One Hundred on National Health.

Letters of the Late Dr. N. S. Davis Wanted

To the Editor:—Will you kindly request your readers to send me any letters in their possession written by my father, Dr. N. S. Davis, or, if they are unwilling to part with the originals, to send me copies. Moreover, if any of your readers know where such letters are I shall deem it a favor if they will inform me. Original letters written by my father or other matter of biographic interest will be preserved and ultimately permanently cared for by the Chicago Society of Medical History.

N. S. Davis, Jr., Chicago.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THUJA OIL IN CORNEAL OPACITIES

To the Editor:—Please give me information on thuja oil as used in corneal opacities, with especial reference to the amount of reaction it will cause, painfulness of the application and benefit from its use. One drop three times a day is recommended to be used. Is that too frequent? Will it be necessary to specify *Thuja occidentalis* in ordering, or is that the only variety used for oil? G. R. T.

Answer.—*Thuja occidentalis* is the only species of *Thuja* commonly used in medicine, and no doubt the oil from this species will be supplied when thuja oil is called for. The essential oil derived from *Thuja occidentalis* and other conifers (including the oil or spirits of turpentine) when dropped into the conjunctival sac sets up a sharp but transitory sclerocorneal congestion and thus stimulates absorption of certain opacities within the cornea itself. The effect thus produced is probably slight, and when the opacity is due to scar tissue, such oily irritants are of no value whatever. Indeed, the great majority of corneal opacities are not removed by this remedy, and it is certainly less valuable than massage with stimulating ointments, the use of thiosinamin and other remedies. If employed at all, thuja oil should be instilled once a day, one drop being put in every three minutes until three drops are used. If the pain and reaction are too great, the remedy should be diluted with sweet oil of almonds.

The Public Service

Medical Department, U. S. Army

Changes for the week ended June 18, 1910:

Holmes, T. G., M. R. C., Par. 2, S. O. 136, relieved from active duty in Medical Reserve Corps at expiration of 1 month leave of absence.

Brownlee, C. Y., major, Par. 3, S. O. 136, granted 3 months' leave of absence.

Siler, J. F., capt., Par. 6, S. O. 137, W. D., granted leave of absence for 1 month on or about July 1, 1910.

Pinquard, Jos., M. R. C., Par. 21, S. O. 137, W. D., relieved from duty at Fort Moultrie, S. C., and ordered to his home.

Pyles, W. L., capt., granted leave of absence for 3 months and 15 days on his arrival in the United States from the Philippine Islands.

Warriner, B. B., M. R. C., *ordered to U. S. Military Prison, Alcatraz* Island, Cal., for duty.

Buck, C. D., major, granted leave of absence for 1 month, to take effect on or about July 10, 1910.

Smart, W. M., capt., ordered from Fort Flagler, Wash., for duty.

Mills, F. H., M. R. C., ordered from Fort Flagler, Wash., to Fort Walla Walla, Wash., for duty.

Sheep, W. L., M. R. C., arrived at Fort Meyer, Va., for temporary duty.

Manly, Clarence J., major, ordered to accompany 25th Infantry from Fort Douglas, Utah, to Fort D. A. Russel Target and Maneuver Reservation, Wyo., for duty.

Morgan, N. D., cont. surgeon, ordered to accompany 4th Infantry from San Francisco to Fort Crook, Neb.

Pinkston, O. W., capt., ordered to proceed to Fort D. A. Russel, Wyo., for temporary duty.

Oliver, Robert T., E. & S. D. surgeon, relieved from duty at Fort Hamilton, N. Y., and ordered to the Philippine Islands, for duty.

Michie, H. C., Jr., M. R. C., ordered to Fort Myer, Va., for station and duty.

Eber, Albert H., M. R. C., on withdrawal of troops from Fort De Soto, Fla., will proceed to Fort Moultrie, S. C., for station and duty.

Clayton, Jene B., major, granted 14 days' leave of absence.

Dulin, Charles T., M. R. C., ordered to Army General Hospital, Fort Bayard, N. Mex., for observation and treatment.

Medical Corps, U. S. Navy

Changes for the week ended June 18, 1910:

Heneberger, L. G., medical director, ordered to command the Naval Medical School Hospital, Washington, D. C.

Harmon, G. E. H., medical director, retired, detached from command of the Naval Medical School Hospital, Washington, D. C., and ordered home.

Richards, T. W., surgeon, detached from the Naval Dispensary, Washington, D. C., and ordered to continue other duties.

Neilson, J. L., detached from the bureau of medicine and surgery, Navy Department, and ordered to duty at the Naval Dispensary, Washington, D. C.

Thomas, G. E., asst.-surgeon, detached from the *Wabash* and ordered to the *Paducah* and to additional duty with a marine detachment.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended June 15, 1910:

Lavinder, C. H., P. A. surgeon, granted 1 day's leave of absence en route in Europe, under paragraph 189, Service Regulations.

Vogel, C. W., P. A. surgeon, leave for 10 days from June 1, 1910, amended to read 7 days.

Bahrenburg, L. P. H., P. A. surgeon, granted 4 days' leave of absence from June 2, 1910, on account of sickness.

Kolb, Lawrence, asst.-surgeon, granted 7 days' leave of absence from June 9, 1910, under paragraph 191, Service Regulations.

Branham, H. M., acting asst.-surgeon, granted 4 days' leave of absence from June 14, 1910.

Friedman, H. M., acting asst.-surgeon, granted 2 days' extension of annual leave from June 4, 1910, on account of sickness.

Rodman, J. C., acting asst.-surgeon, granted 12 days' leave of absence from June 13, 1910.

Schwartz, Louis, acting asst.-surgeon, granted 7 days' leave of absence from June 6, 1910, under paragraph 210, Service Regulations. Granted 14 days' leave of absence from June 14, 1910.

Storrs, H. R., acting asst.-surgeon, granted 7 days' leave of absence from July 5, 1910.

Walkley, W. S., acting asst.-surgeon, granted 3 days' leave of absence from June 20, 1910.

Board of medical officers convened to meet at the Bureau June 20, 1910, for the examination of candidates for admission to the service. Detail for the [illegible] P. McIntosh, chairman; Surgeon W. G. Stimpson, [illegible] Surgeon A. M. Stimson, recorder.

Optometry Bill Vetoed in Ohio.

Evidently the governors of our states are having their eyes opened to the viciousness of the optometry bills which are occasionally passed by state legislatures. The bill passed in Maryland several weeks ago was promptly vetoed by the governor. In Massachusetts and New Jersey the bill was defeated in the legislature. The optometry bill which passed the Ohio legislature was vetoed by Governor Harmon in a message clearly stating his reasons for refusing to approve the measure. We commend Governor Harmon's message to the careful consideration of the governors in any other states in which such bills may be passed by the legislature. Governor Harmon says:

> "Amended Senate Bill 51, entitled 'A bill to regulate the practice of optometry,' creates a board of five members to examine and license persons to practice 'optometry,' which it defines as 'measurement of powers of vision and adaption of lenses for the aid thereof by any means other than the use of drugs, medicine or surgery.'
>
> "The express exemption of mere dealers in spectacles and eye glasses, and the requirement that the examination shall include 'anatomy and physiology of the eye,' as well as 'optics and such other subjects as said board may decide to be suitable and proper,' show that the proposed license is to cover something more than the mere commercial supplying of eye lenses to customers.
>
> EYE PART OF SYSTEM
>
> "That something is necessarily, from its nature, a part of the field covered by medical science. Our statute (G. O. 1286) includes in the definition of that field the prescribing, advising, recommending, administering or dispensing, for a fee or compensation, not only of drugs or medicines, but of appliances for the cure or relief of a bodily injury, infirmity or disease.
>
> "It is beyond question that the eye is so connected with the general system that the subject of impaired or imperfect vision cannot properly be considered as though it were an independent function, and it is conceded that, especially with children, the condition and needs of the eye cannot, in a great many cases, be known without the application of drugs for dilation, as well as the examination of other bodily conditions.
>
> LEADS TO GRAVE PERIL
>
> "So to set men who have not themselves had medical education and stood the careful tests required by law in the interest of the public health to examine and license others to deal with one of the most delicate and important organs appears to me a step downward leading to grave peril. And if what may be called the mere mechanical treatment of defective vision is to be made a special branch of medical practice, it should be under the jurisdiction of the state medical board, so that the proper qualifications may be judged by men of approved education and training in the general science which dealt with the ills of the human body.
>
> "But I know of no special branch of medical practice which is itself split up as is proposed here. All other special branches are complete in themselves, and no one is permitted to engage in them unless he is qualified to diagnose and deal with cases in all the aspects they may present.
>
> GREAT SKILL NEEDED
>
> "One who is not skilled in optical surgery and medicine surely cannot be safely trusted to tell whether these are not required instead of the mechanical treatment he is able to give, and the time lost in discovering the need of these will often make resort to them useless.
>
> "Schools of optometry are mentionel in the bill, but it is shown by the evidence presented to me that such as there are generally, if not always, lack of requirements of proper education for so important an art as treating the human eye. Many of them are mere correspondence schools.
>
> "It is true that dealing with vision ought to be strictly regulated, because, to common knowledge, much harm is done by itinerant and other persons who profess to supply the needs of the people. But I do not think this bill furnishes the proper means of regulation.
>
> PUBLIC WOULD SUFFER
>
> "On the contrary, by giving the authority of the state to many who lack the proper education and training, as this bill would, in my judgment do, the public would be misled as to their qualifications. Those so lacking would undoubtedly outnumber those who merely by special talent and practice would acquire a certain proficiency, as men do in all callings.
>
> "Druggists often gain a knowledge of diseases and their remedies as extensive as some physicians have, yet they are not permitted to apply that knowledge in practice, because such cases are exceptional.
>
> "For these reasons I herewith file the bill with the Secretary of State unapproved. Judson Harmon, Governor."

Homeopathic Society Endorses Owen Bill

The following preamble and resolution in reference to the Owen bill were adopted by the Homeopathic Medical Society of the County of New York:

> WHEREAS, In the public [illegible] ve been made that the practitioners of the [illegible] medicine are opposed to this bill, the Hom[illegible] of the County of New York, at its regular meeting, June 9, 1910, passed the following resolution:
>
> *Resolved*, That the Homeopathic Medical Society of the County of New York heartily endorses the proposed national Department of Health, feeling that such a department will increase the efficiency of state boards of health, and will produce a unanimity of action which is essentially lacking under the present conditions.
>
> WILLIAM FRANCIS HONAN, M.D.,
> President.
>
> JOHN STROTHER GAINES, JR., M.D.,
> Secretary.

Marriages

HOWARD KAHN, M.D., to Miss Florence Ring, both of Baltimore, June 8.

MAX LOUIS MENDEL, M.D., Chicago, to Miss Marie Hughes of Vicksburg, June 8.

WILLIAM CARVER FORDER, M.D., to Miss Annie Laurie, both of St. Louis, Mo., June 6.

ARTHUR G. HYDE, M.D., to Miss Carrie L. Cook, both of Cleveland, Ohio, June 15.

NORMAN HAYES PROBASCO, M.D., to Miss Olive Koons, both of Plainfield, N. J., June 7.

WILLIAM MACKEE CROSIER, M.D., Alexis, Ill., to Miss Louise Lafferty of Chicago, June 8.

DANIEL SEWARD BROSNAN, M.D., to Miss Mary Ruth Davis, both of New Orleans, June 13.

MURRAY A. RUSSELL, M.D., Washington, D. C., to Miss Louise Joyce of Chicago, June 9.

ISIDORE CHARLES RESHOWER, M.D., to Miss Miriam Cardozo, both of New York City, June 15.

ALPHONSE M. BODDEN, M.D., Milwaukee, to Miss May Genevieve Riley of Portage, Wis., June 1.

WILLIAM HAROLD WICKETT, M.D., Anaheim, Cal., to Miss Chapman of Placentia, Cal., June 4.

ANDREW HAVEN CLEVELAND, M.D., Boston, and Aurelia Puderer, M.D., of Belleville, Ill., June 8.

GEORGE RILEY TUBBS, M.D., to Miss Bessie Florence Whitehead, both of West Point, Ind., June 7.

JOHN MONTGOMERY GELWIX, M.D., to Miss Mary Sherman Crall, both of Chambersburg, Pa., June 1.

FREDERICK OSCAR TONNEY, M.D., Chicago, to Miss Clara Evelyn Sanborn of St. Paul, Minn., June 4.

LAWRENCE KOLB, M. D., U. S. P. H. and M.-H. Service, to Miss Lillian H. Coleman, at Baltimore, June 9.

JULIUS LAWRENCE MOGULESKO, M.D., New York City, to Miss Dora R. Salzenstein of Chicago, June 12.

WILLIAM CHASE MUDGETT, M.D., to Miss Edith Cecilia Heizmann, both of Southern Pines, N. C., June 8.

WILLIAM EDWIN BAYLOR, M.D., Cedar Bluff, Va., to Miss Annie Sylvester Doughty, at Cedar Bluff, June 8.

HENRY C. MADDUX, M.D., M. R. C., U. S. Army, to Miss Katharine R. Oliver, at Charlottesville, Va., May 20.

JAMES GLEN REA, M.D., Wellington, Kan., to Miss Frank Kathryn Tucker of Fort Madison, Iowa, May 11.

Deaths

Louis Clark Pettit, M.D. University of Pennsylvania, Philadelphia, 1883; formerly a member of the American Medical Association; American Medico-Psychological Association, and New York Academy of Medicine; for 23 years a member of the staff of the Manhattan State Hospital, Ward's Island, New York; a recognized authority on nervous diseases, and particularly paresis; died in St. Alexis Hospital, New York City, June 3, from arteriosclerosis, aged 52.

Richard Crain Dean, M.D. Jefferson Medical College, 1854; of Washington, D. C.; rear admiral U. S. Navy, retired on account of age limit, May 27, 1895, after ten years and nine months sea service and twenty-six years and two months shore duty; from 1870 to 1874 he was assistant chief of the Bureau of Medicine and Surgery; from 1876 to 1877 he was fleet surgeon of the North Atlantic Fleet; died at his home, June 9, aged 77.

Edwin Wilson Rhea, M.D. Jefferson Medical College, 1901; a member of the Medical Society of the State of Pennsylvania; one of the physicians in charge of the State Institution for the Feeble Minded of Western Pennsylvania, Polk; died in that institution, June 8, from specticemia, following appendicitis, aged 32.

John Philip Henriques, M.D. Yale University, Medical Department, New Haven, 1878, and valedictorian of his class; afterward graduated from the University of Heidelberg; died at his home in Edgewood, Providence, June 6, a year after an operation for gallstones, aged 53.

A. D. James, M.D. University of Louisville (Ky.) Medical Department, 1870; United States marshal for two terms, and congressman for two terms; died at his home in Penrod, Ky., June 7, from Bright's disease, aged 60.

Charles M. Johnson, M.D. University of Pennsylvania, 1850; a practitioner of St. Charles county, Mo., for more than fifty years and the oldest physician of the county; died at his home in St. Charles, June 7, aged 84.

Benjamin Helm Peabody, M.D. Cleveland Medical College, 1848; a surgeon in the Federal Army during the Civil War; died at the home of his daughter in Pittsburg, June 9, from heart disease, aged 85.

James Holmes Wikoff, M.D. New York University Medical College, New York City, 1854; a member of the Medical Society of New Jersey; of Princeton, N. J.; died at Atlantic City, June 8, aged 78.

Edgar C. Rankin, M.D. Kansas City Medical College, Kansas City, Mo., 1888; a member of the American Medical Association; of McLouth, Kan.; died at St. Mary's Hospital, Kansas City, June 1, aged 57.

Edmund Stevens, M.D. Albany (N. Y.) Medical College, 1898; deputy coroner of Ramsey county, Minn., of St. Paul; died at the City Hospital in that place, June 11, from pleuropneumonia, aged 34.

Carl August A. Bruck, M.D. Wisconsin College of Physicians and Surgeons, Milwaukee, 1896; a member of the State Medical Society of Wisconsin; died at his home in Milwaukee, June 10, aged 54.

Frank T. Lindsay, M.D. Howard University, Washington, D. C., 1875; a prominent colored practitioner of Xenia, Ohio; died in his office in that city, June 2, from heart disease, aged 54.

Henry R. Maxson, M.D. New York Homeopathic Medical College, 1880; of Nortonville, Kan.; a veteran of the Civil War; died at the home of his son in Cunningham, Kan., June 2, aged 71.

Carl Schilling, M.D. Missouri Medical College, St. Louis, 1880; a member of the American Medical Association; of Fort Wayne, Ind.; died at his home in that city, June 12, aged 56.

Henry R. Field (license, Mo., 1884); for 43 years a practitioner of medicine of Rockville, Mo.; postmaster in 1892; died at his home, May 19, from gastric ulcer, aged 72.

Daniel Merritt Griffen, M.D. College of Physicians and Surgeons, New York City, 1891; of Port Chester, N. Y.; died at Hot Springs, Va., June 3, from nephritis, aged 44.

William Carpenter Comstock, M.D. Hahnemann Medical College and Hospital, Philadelphia, 1896; died at Sudbrook Park, Baltimore, June 5, from heart disease, aged 38.

Charles Frederick Moore, M.D. Rush Medical College, Chicago, 1888; a member of the Illinois State Medical Society; died at his home in DeKalb, June 10, aged 48.

Carl P. H. Buck, M.D. Copenhagen, Denmark; a resident of California since 1854, and a Civil War veteran; died in Santa Rosa, May 19, from mixed sarcoma, aged 75.

Edgar Martin, M.D. Cleveland Medical College, 1856; a pioneer practitioner of Huron county, Ohio; died at Norwalk, Ohio, June 8, from pneumonia, aged 84.

William H. Gibbs, M.D. Medical College of Virginia, Richmond, 1862; a Confederate veteran; died at the home of a nephew in Richmond, June 5, aged 75.

Warren Andrus James, M.D. Bellevue Hospital Medical College, New York City, 1865; died at his home in Brooklyn, June 2, from heart disease, aged 71.

Charles A. Burleigh, M.D. California Eclectic Medical College, 1889; of Forest Hill, Cal.; died at that place, June 3, from pneumonia, aged 47.

James Allman Dixon, M.D. Hahnemann Medical College, Chicago, 1884; died at his home in Bellaire, O., June 10, aged 53.

George W. Swartout (*license*, Mich., 1900, twenty-three years' practice); of Aurelius, Mich.; died at Ann Arbor, June 9, aged 80.

Charles Ferris, M.D. Pulte Medical College, Cincinnati, 1895; died at his home in College Hill, Cincinnati, June 4, from hepatitis, aged 35.

Lewis J. Fabian, (license, Pa., 1884); died in Philadelphia, February 23, from epithelioma of the tongue, aged 70.

Angus Macdonald, M.D. Boston University, 1876; died at his home in Boston, June 1, from pancreatitis, aged 65.

John R. Gardiner, M.D. Rush Medical College, 1876; died at his home in Wichita, Kan., May 27, aged 62.

Henry Thomas Simmons. Dr. Henry Thomas Simmonds, Shamokin, Pa., advises us of an error in the death notices of June 11. The deceased was not a graduate of the University of Pennsylvania, Philadelphia, 1908, nor was he located at Altoona, but was a senior student in Western Reserve University, Cleveland. The similarity of both christian and surnames was the occasion for this error.

Society Proceedings

COMING MEETINGS

Maine Medical Association, Bar Harbor, June 29-30.
New Jersey Medical Society, Atlantic City, June 28-30.

NEW HAMPSHIRE MEDICAL ASSOCIATION

One Hundred and Nineteenth Annual Session, held at Concord, May 12, 1910

The President, Dr. Frank Blaisdell, of Goffstown, presiding

Officers Elected

A list of the newly elected officers appeared in The Journal, May 28, p. 1795. Concord was chosen the next meeting place for May 11 and 12, 1911.

President's Address: Medicine in New Hampshire

Dr. F. Blaisdell reviewed the history of the association and gave a brief résumé of 120 years of New Hampshire medicine and the indebtedness of the state to the medical profession. He made special reference to Dr. Josiah Bartlett, the first signer of the Declaration of Independence after the President had signed it; Matthew Thornton, a member of the Continental Congress in 1776; David L. Morrill, United States Senator in 1824, also governor; Noah Martin, former senator and governor; the present governor, Henry B. Quinby; and United States Senator, Jacob H. Gallinger. He commended the work of the State Board of Health in securing the passage of a bill granting money to build a state sanatorium at Glen Cliff. He spoke of the need of more laboratories; also that its work should be extended to the prevention of loss of life by preventable accidents on railroads and in shops, to sweatshop methods, and poisoning while working with chemicals, the prevention of criminals and the physically unfit from marrying, and the sterilization of those whose children would only increase the criminal class. Reference was also made to Dartmouth College and its work for 112 years.

Secretary's Report

Dr. D. E. Sullivan: One of the principal events of the year was the visit, early in October, of Dr. J. N. McCormack of Kentucky. Chairman of the Committee on Organization of the American Medical Association, and I do not know of any one thing in recent years that has left such a profound impression on the minds of both the profession and the laity as the sentiments he expressed. Addressing the doctors in the day and the public at night in his characteristic forceful manner, he delighted large audiences at Keene, Claremont, Woodsville. Berlin, Laconia, Concord and Manchester. Our only regret was that other sections of the state were not favored. As was anticipated, the realization of the radical changes in our constitution and by-laws has not been accomplished without some misunderstandings. To-day, however, most of the county officers and members have a fairly definite conception of the essentials. I would suggest that you advise the component societies to have more frequent meetings; to combine the offices of secretary and treasurer, with a salary commensurate to the duties; and to have January 1 the beginning of the fiscal year.

The Owen Bill

On the recommendation of the Committee on Public Policy and Legislation. the following resolutions were adopted:

Whereas, Sanitary science has demonstrated its ability to protect and to prolong human life, we believe that the diversified federal activities for the public health interests of this great country, those now existing and those that could be inaugurated for the further protection of human life, should be assembled under a Department of Public Health; therefore

Resolved, That we approve the provisions of Senate Bill No. 6049, to establish a Department of Public Health, and we respectfully ask our senators and representatives in Congress to give due consideration to the voice of the New Hampshire Medical Society herein expressed.

Resolved, That the secretary of this society be directed to transmit a copy of the foregoing preamble and resolution to each of the New Hampshire senators and representatives in Congress.

Report of the Committee on History

It was agreed that the written transactions of the society and of the council from the organization of the society in 1791 to the year 1854, inclusive, be printed, same to be in the original phraseology, spelling, punctuation, etc., of the manuscript records. The committee stated the desirability of authorizing the full and complete indexing of the work, and of giving them authority to include a list of the members of the New Hampshire Medical Society from its organization to the present time. The treasurer suggested that the names of the members of the society be included up to the time of 1854 and the names of those who have joined since omitted.

Alcoholism

Dr. Harry E. Mygatt, Nashua: There is no greater evil, no more extensive and widely spread disease than that of alcoholism, with sociability one of the great causes. I do not believe that alcohol is a food. Alcoholism should be regarded as a disease producing vice and a vice-producing disease. It is a potent factor in the development of mental and nervous diseases, surpassing all other causes. Its treatment should be conducted along three lines, namely: Influences which incite or strengthen moral resolutions; medicinal; controlling enforced abstinence. The one *sine qua non* of genuine treatment is unconditional abstinence from everything intoxicant. The present treatment of inebriate offenders against the law is neither curative nor deterrent. He recommended the necessity of greater attention to neurotic and psychopathic indications, and advocated the enactment of laws providing their commitment to suitable institutions for scientific treatment.

Asthma in Relation to the Nose

Dr. Thomas W. Luce, Portsmouth: Some authors say asthma is never due to trouble within the nose, while some specialists claim all cases can be traced to the nose. Such extreme views are not accepted by the profession. In 1902 Dr. Alexander Francis of London, by cauterizing the septal mucous membrane, was able, in a large number of cases, to relieve asthmatic attacks. Cases with polypi constitute the least hopeful cases for permanent relief. In forty-two cases treated during the last three years results under this treatment were more satisfactory than any other ever employed. General treatment was not neglected and a number were given iodid of potash.

DISCUSSION

Dr. Charles C. Rogers, Farmington, commended the treatment.

Dr. Frank E. Kittredge reported cases of asthma cured, or greatly relieved, by operations on the nose, such as removal of polypi and correction of a deflected septum.

Incipient Pulmonary Tuberculosis

Dr. P. Challis Bartlett: It is apparent that the increased knowledge of this disease has made it a personal affair with everyone. It is, of course, needless to say that the earlier the diagnosis is made the greater the prospect of complete cure. Many cases of tuberculosis develop insidiously after an attack of pneumonia. Professor Fisher places the economic loss to a community for each death from tuberculosis at $8,000. The whole aim is to build up the body, thereby increasing the natural resistance, and only by the observance of the little details can this be done, with strict cooperation between the patient and physician. The patient should be told that there may be set-backs, but that by sticking to it most patients may look for a complete cure. We know that tuberculosis is preventable, and that education will reduce the number of cases very rapidly. The work that has been done in the last two decades has changed what was considered an incurable disease into a curable one.

DISCUSSION

Dr. J. M. Gile: I wish to refer briefly to the broad features of the great battle that is now on against this disease that has so black and so fatal a history. The weapon with which we fight the disease from now on is knowledge, and that knowledge is based on the fact that we know the life history of the germ that precedes the disease. Suppose to-day you could quarantine and should quarantine every individual and every animal that has active tuberculosis as you would quarantine like cases of leprosy. One generation in the human race would practically wipe out tuberculosis. In regard to the state sanatorium, it is established as an institution for educational purposes and for the taking of incipient cases that should be curable; so please remember the principle of the institution and do not send incurable patients.

Some Tendencies in Modern Medicine

Dr. John W. Staples, Franklin: It is in the rôle of preventive medicine that its greatest and most fruitful victories have been won. Every water supply and every milk supply must give an account in the laboratory of the work done in the body. This advancement in preventive medicine means that the valuable colleges must graduate less men and men better equipped. It means, without a rearrangement of value, a diminishing amount of income to take a strong stand in favor of adequate pay from town and city officers. I wish that conditions were such that no physician would do contract work, and I ask for a rigid examination as to the ability of patients entering hospitals to pay the physicians for his services. I wish to endorse the postgraduate course recommended by the American Medical Association.

DISCUSSION

Dr. Abram W. Mitchell, Epping: Without any question, medicine has so many tendencies that it would be impossible for a man to anticipate what a writer or speaker would take up. We are really in a stage of transition from methods ancient and methods modern. Medicine is now coming grandly and scientifically into its own as a more exact science, and I believe that our relations with each other and with our patients are changed and the change is not always due to us. I believe that the patient is learning to look on his doctor more as a pilot than a wrecker.

Dr. James B. Woodman, Franklin: Our public health officers will hold a more important place and will be better paid; will be given more authority, a broader scope and will be more efficient. All our state institutions will be given greater scope and will do more and better work. This means an enormous cutting down of disease and the gathering together of much of it that remains in large centralized institutions.

(To be continued)

CANADIAN MEDICAL ASSOCIATION

Forty-third Annual Meeting, held in Toronto, Canada, June 1-4, 1910

The President, Dr. R. J. Blanchard, Winnipeg, in the Chair

Addresses of welcome were delivered by Dr. Rine, Minister of Education for Ontario, representing the Provincial Government; Mr. Ward, representing the City of Toronto; and Dr. R. A. Falconer, representing the University of Toronto. The president for the year, Dr. Adam H. Wright, Toronto, was then inducted into office.

President's Address: Medical Education, the General Practitioner and the Surgeon

Dr. Adam H. Wright, Toronto, stated that the medical student of the present day was overburdened with subjects in his curiculum and that in order to develop into a useful medical practitioner he needed to be taught less and to learn more. Dr. Wright believed that not infrequently the modern surgeon was rather inclined to exhibit his own swill than to attempt to impart his knowledge to the medical student and to the general practitoner.

Report on Pasteurized Milk

Dr. Charles J. C. O. Hastings, Toronto, secretary of the milk commission appointed about two years ago by the Canadian Medical Association, presented the report. Dr. Hastings mentioned the large infant mortality in Ontario and in Canada generally and stated his belief, and the belief of the commission, in the merits of pasteurization, which he said, destroyed hurtful germs without impairing the nutritive qualities of the milk. The commission had cooperated with the milk dealers of Toronto so that a very considerable quantity of officially pasteurized milk and cream was now sold in that city. The outlook, he said, so far as a better milk-supply for Canada was concerned, was exceedingly hopeful.

Dr. Charles E. North, *New York City, was also in favor* of pasteurization. He said that out of 300 guinea-pigs he had inoculated with samples of New York milk, half of those inoculated with raw milk had died, one of those inoculated th commercially pasteurized milk, and none of those inocu- ed with certified milk.

Prof. A. McGill, *Dominion Analyst, said that before any* steps could be taken in the direction of legislating for a pure milk-supply, it was necessary that a specific definition should be made of pasteurized milk, which at present it was very difficult to correctly define.

J. G. Rutherford, Veterinary Director-General of Canada, *emphasized the necessity of stamping out tuberculosis in cows* if it were desired to eradicate the disease in the human species. Of course Dr. Rutherford is a firm upholder of the theory that *bovine tuberculosis is transmissible to man and is an advocate* of very drastic measures of prevention.

Address in Medicine: Bright's Disease

Dr. W. P. Herringham, Physician to St. Bartholomew's Hospital, London, Eng., said that nephritis should be a subject of especial interest to physicians in America, as, according to statistics, it is rapidly increasing in the cities of this continent. He dwelt on the fact that acute nephritis was very rare in England and that the disease generally had an insidious course. He pointed out that the presence of albumin in the urine was not the only symptom, nor the lesions of the glomeruli the only lesions, but that the greatest harm wrought by an attack of nephritis was the delicacy of the parts affected as a result, and the liability to recurrence. With respect to the exciting cause, Dr. Herringham said that it was almost impossible to dogmatize. A patient afflicted with Bright's disease might be compared to a town of which the drainage system is out of order. Diet was a very important factor of treatment, but although the nitrogenous constituents of food should be largely avoided, Dr. Herringham was not in favor of the diet being restricted to fish or being regulated on hard *and fast lines. He said that* light ordinary diet was satisfactory; and he had found that patients did better on flesh than on milk. Strict moderation should be observed as to quality in diet, but considerable latitude might be allowed as to variety. Exercise and fresh air were beneficial but exposure should be guarded against and warm clothing worn, especially *around the loins.* The chief object in serious cases should be to avoid uremia by exciting the excretions of urine. Milk was sometimes effective for this purpose and he employed saline diuretics, cardiac stimulants and alkaloids as circumstances seemed to indicate. Dr. Herringham said that according to his experience hematuria was most difficult to control. For the edema so often present, the safest way, if possible, was to drain by cannulas. Deprivation of salt was useful in some of the milder cases. Regarding the high blood-pressure, in those suffering with Bright's disease, the speaker said that he looked on this symptom as one of compensatory action and in young persons as not serious. The arteries of the young were elastic and capable of much tension. In old people, and after 50. high blood-pressure was dangerous for the obvious reason that the arteries were brittle and frail. In certain cases venesection might be valuable, and might prevent the poison in the blood *from passing* the bounds of tolerance. The wonderful point in connection with renal disease, in the opinion of Dr. Herringham, was not that the patients died, but that some of them *lived as long as they did live. Possibly* the continued presence of the poison in the system established a certain degree of immunity of its own.

Publication of Journal Recommended

The association council recommended that the association *should bring out a journal* of its own forthwith, with Dr. Andrew McPhail, of Montreal, as editor, which should absorb the *Montreal Medical Journal.* This recommendation was adopted.

Dominion Registration

Dr. T. G. Roddick produced an amended bill on Dominion registration. In this the principal change was that the *Dominion should not define the qualifications necessary for* matriculation in the study of medicine and for obtaining the provincial license, this, as formerly, being regulated by the *provincial authorities.*

Address on Surgery: Surgery of the Joints

Dr. John B. Murphy, Chicago, said that in joint injuries it was the capsule that gave the surgeon the most trouble. Considered from a pathologic standpoint, he said, the capsule was a non-vascular fibrous tissue, an inelastic structure difficult of dstruction and that its non-vascularity made inflammation of joints especially difficult to treat properly. Draining a joint was, as a rule, wrong because the endothelial layer was thereby destroyed. The object in order to save a joint from ankylosis was not to lay it open but to close it. By means of animal experimentation and by accurate observation of human subjects, Dr. Murphy thought that it had been demonstrated that inflammation of the joint was not rheumatic in character but metastatic, the rational treatment, therefore, was to relieve the condition which destroyed. Aspiration and not opening of joints was indicated. The aspiration should be done with formalin and glycerin or sometimes with turpentine. *Treatment should be pursued promptly before pathologic* processes had had time to effect their destructive work. He said that it might be taken as a surgical axiom that every acute infectious process in a joint could lead to ankylosis by pressure; to avoid this the limb should be kept extended. Formalin and glycerin should be injected seven or eight days before operative treatment of the patella and if this were done no effusion would occur.

Symposium on Exophthalmic Goiter

Dr. S. P. Beebe, New York, pointed out that Graves' disease was not always a functional disturbance of the thyroid gland. The hypertrophied condition of the gland varied considerably in different cases; its secretions also altered in type with the progress of the disease. As a matter of fact, clinical *conclusions often clashed with pathologic findings.* Laboratory studies showed that the exact conditions of exophthalmic goiter could not be reproduced in animals *although conditions* could be reproduced resembling these in most respects. Dr. Beebe uttered the warning that iodin was readily taken up by the gland in Graves' disease and unless caution were observed the clinical results might be fatal. A serum for the treatment of exophthalmic goiter had been prepared by inoculating animals with proteids *from human thyroid gland* and Dr. Beebe was understood to say that the limited administration of the serum had been attended with satisfactory results.

Dr. A. McPhedran, *Toronto, said that* the disease was not prevalent in Canada. In the General Hospital, Toronto, during the past five years there had been 55 cases out of a total of *8,000 medical cases; of surgical cases* there had been in the same hospital about 0.5 per cent. With regard to prognosis Dr. McPhedran was non-committal and he remarked that surgical writers were skeptical of the utility of medical treatment and statistics seemed to justify this attitude. Statistics, however, were naturally more favorable to the surgical side of the *argument than to the medical.*

Dr. F. H. Shepherd, Montreal, believed that surgical treatment of the disease was by no means ideal; he looked for a *vaccine or serum treatment* as the only rational mode of removing the cause. Surgical treatment, he said, often relieved and sometimes cured but physicians did not generally send patients to surgeons until the disease was too far advanced for operative measures to be wholly successful. He thought that the extremely excitable state in which sufferers from this malady were wont to be was the cause of many unsuccessful operations and he had tried, with some favorable results, the policy of operating without giving the patient a previous intimation of the decision to do so. When the operation is performed it should be done rapidly and the parathyroid should be left in position as nearly as possible.

In the discussion which followed the most important point brought out was that in a very large number of cases the tachycardia was not relieved by operation.

Address in Gynecology: Old and New Gynecology

Dr. Henry C. Coe, New York, praised the giants of the past, such as Lawson Tait, Sims, Emmet and Thomas, and deplored many of the modern operative fads which American gynecologists and obstetricians in particular had so blindly taken up. He pointed out that most of these bizarre operations had died a natural death. With the marvelous increase in skill in abdominal surgery, he said, there had been but little decrease in the death-rate from puerperal sepsis. Of course, this was more a question of aseptic surroundings than of surgical skill and was due to the fact that the housing of the poor in all large cities was still very defective. Prophylaxis should be the keynote of general medicine. Dr. Coe stated that he believed that marriage would one day be subject to state control. He said that this was no fanciful dream but well within the realms of practical politics.

Medical Education and Inspection

Dr. J. C. Connel, Kingston, Ont., proposed the appointment of a committee to deal with the subject of medical education. This was agreed to and a committee was formed. A report advocating the adoption of a system of medical inspection in all the schools of Canada was presented by Dr. John Stewart of Halifax and as a result a special committee was appointed to consider the question.

Election of Executive Council and Appointment of Officers

The following were elected for the ensuing year to the Executive Council: I. C. Fagan, Vielorid, B. C.; D. Ingersoll, Olmsted, Hamilton; George E. Armstrong, Montreal; A. I. Shillington, Ottawa; James Bell, Montreal; F. N. G. Starr, Toronto; J. T. Fotheringham, Toronto; J. H. Elliott, Toronto; John Stewart, Halifax; R. A. Reeve, Toronto; A. McPhedran, Toronto; Murray Maclaren, St. John, N. B.; Alex. McNeill, Charlottetown; J. D. Lafferty, Calgary; and F. G. Finley, Montreal.

The following officers of the Association were appointed for the coming year: President, Dr. George E. Armstrong, Montreal; general secretary, Dr. E. W. Archibald, Montreal; treasurer, Dr. H. B. Small, Ottawa; vice-president for Quebec, Dr. Simord, Quebec; local secretary, Campbell Howard, Montreal; finance committee: Dr. James Bell, Montreal; Dr. J. L. Fotheringham, Toronto, Dr. Murray Maclaren, St. John, N. B., Dr. S. J. Tunstall, Vancouver, B. C., Dr. F. N. Starr, Toronto, Dr. F. J. Blanchard, Winnipeg, and Dr. F. B. Finley, Montreal.

9 Primary Tuberculosis of the Nose. S. Oppenheimer, New York.
10 Education and Instruction in Sexual Relations as a Prophylaxis Against Venereal Diseases. A. Ravogli, Cincinnati.

3. **Blood-Pressure in Pregnancy.**—In order to establish a standard of normal blood-pressure from which the deviations could be noted, Hirst has taken the blood-pressure of 100 non-pregnant women, showing no signs of any kidney or heart lesion likely to give misleading results. The average blood-pressure, according to Faught's instrument which was used, was 112 mm. The blood-pressure of 100 normally pregnant women was then taken, who at no time showed albumin or any constitutional sign of toxemia, and this pressure was found to be 118 mm. These figures hold good up to approximately seven and one-half months, past which date there is a gradual rise, so that in the middle of the last month of pregnancy, a fairer average is 124 mm. The blood-pressure increases slightly until subsidence of the uterus takes place, and from then there is no further increase, and frequently a slight fall.

In women showing symptoms of toxemia, however, the picture changes. The blood-pressure in 39 women with eclampsia and 18 who did not have eclampsia but had marked albuminuria at the time the first examination was made, was at its lowest, 142 mm. The highest blood-pressure recorded in a woman without eclampsia was 192 mm.; the highest in an eclamptic was over 320 mm., so high that the mercury ran out of the top of the tube before the pulse was shut off.

4. **Psychology and Psychiatry.**—White says that the greatest change that has come over psychiatric conceptions in recent years is the recognition of the necessity for individual psychologic analysis. As a result of this analysis there has been found a region of mind which is out of the field of complete conscious awareness. In the normal process of mental development constellations of ideas corresponding to frequently repeated adaptations are relegated to this region where they act more or less automatically thus leaving the upper strata free for new and unusual types of reaction. The field of full and clear personal consciousness is this field of new and unusual necessities for adaptation. The field of clear personal consciousness conditions relatively few of our mental states. The complex is a pathologic constellation which is repressed from full expression by the censor of consciousness. The compromise between the effort of the complex to gain expression and the censor to repress produces the phenomena of the psychoneuroses and of dreams. Dreams therefore become the royal road to the subconscious. It is no longer possible to dismiss a mental symptom by recording it or to dismiss a case by simply observing the obvious. Every symptom requires to be analyzed and traced to its ultimate and efficient cause. Only by such methods can it be hoped to help the patient by the application of a rational therapy.

6. **Mercury and Arsenic in Tuberculosis.**—With the hope that antiseptics would enable one to use larger doses of tuberculin without risk, and that the larger doses of tuberculin by their action on the tuberculous areas would insure better penetration of these antiseptics into such places, Penrose gave his patients from one-fifth to one-third of a grain of succinimid of mercury, hypodermically, every other day, until 30 injections had been taken and then started them in with small doses of tuberculin (old tuberculin) hypodermically until a good tolerance dosage was obtained, and then gave this usually every other day, alternating with mercury injections for fifteen days. After a variable period of rest from treatment, from fifteen to thirty days, he gave another course of the mercury alone, etc. He now finds it best to get the tolerance dose of tuberculin first in the untreated case and then he has a gauge as to the amount of tuberculin best to use after the mercurial course. This, he has usually found, is three to four times as large as the initial dose of tuberculin used before the administration of the mercury. In one case especially, Penrose was surprised to find that such a dose every other

day gave no general reaction, although one-fourth of this dose every four or five days before the mercury was started shot the temperature persistently up to 102° F. and more.

8. **Subhepatic Appendicitis.**—In Ingraham's case the patient first had uneasiness and fairly acute pain in the region of the stomach which shifted into the right side of the abdomen and became quite severe. There was some nausea, but no vomiting. The abdomen was rigid in the upper quadrant and soft in the lower. There was moderate tenderness just below the ninth and tenth cartilages, no tenderness whatever at or below the line from the navel to the anterior superior spine of the ileum. Because of the typical onset and pain in the epigastrium, shifting to the right side, the diagnosis of appendicitis was made, with the suggestion that the position of the rigidity and tenderness might be accounted for by the appendix pointing high or due to a high fetal position of the cecum. Operation was decided on.

A high right rectus incision was made, and after a fruitless search for the appendix in the right iliac fossa, the incision was prolonged upward and by following the transverse colon, the cecum was found lying over the right kidney and just below the liver margin. The appendix with a darkened swollen tip pointed upward and outward, arising from a point on the cecum anteriorly and toward the right. The cecum was attached and could not be brought out of the incision.

16 Three Years of Rabies in Indiana. J. P. Simonds, Indianapolis.

13. **Diabetes Mellitus.**—Liebermann regards diabetes mellitus as a neurosis dependent on disturbance of the nerve energy supply to the digestive system. There is a vasomotor paralysis of the splanchnic area, causing hyperemia of vessels about the liver. This is induced by injury or irritation of some nerve of the cerebrospinal system, or injury or irritation of the filaments and ganglia of the sympathetic system. Electricity properly applied will relieve this hyperemia. The high potential and high frequency currents are the proper ones to use. The indirect positive static spark or brush, with negative insulation, or the same polarity in high frequency effleuve is applied over the epigastric region and celiac plexus. It has a sedative, pleasant effect and causes sleep. The symptoms subside gradually and sugar disappears.

15. **Treatment of Progressive Scoliosis.**—Strunksky advocates a system of treatment of scoliosis which dispenses with the corset or other support as not only unnecessary, but harmful, and makes use of exercises in the horizontal position, with prolonged rest on the back. In this position deformity disappears, while in the upright posture it is present. At the same time everything is done to increase the tone of the nervous system and the general condition. He allows creeping exercises, and exercises of the shoulders and trunk in the horizontal position, with pelvis or body strapped to the table. There is a wider range of excursion for the vertebræ, a wider amplitude of muscular contraction, a tendency to restore the muscles to their normal length, and relief for the vertebræ from the superincumbent weight.

22. **Taking Casts for Flat-Foot Plates.**—In Fitzsimmons' method the patient is placed seated or in dorsal recumbency on a table, the edge of which reaches to mid-calf. Two 5-inch plaster bandages enveloped in the original newspaper covering, with the free end of the bandage folded back for about one inch are placed in a dish of warm water, deep enough to cover it, and left there until no bubbles of air arise to the surface.

The bandage is then taken out of water and the paper removed. The free end for about 3 inches is unrolled and allowed to hang while the plaster is loosely held in one hand (right). With the other hand (left) the strip is grasped at the middle and placed on the dorsum of the foot over an imaginary line passing down the dorsum of the foot from midway between the two malleoli to the space between first and second toes. This strip is now fastened to the foot by circular turns of plaster, rapidly but smoothly, from the terminal joint of the toes to malleoli. When the bandage has been fastened it should be molded to the foot gently, without undue pressure, and the foot held at right angles to leg with toes neither flexed nor crumpled. This can easily be done by just holding the palm of the hand flat against the sole of the foot so that both the heel and the metatarsal pad and the toes are just lightly touched. The plaster thus applied will harden rapidly, and in a few minutes with a sharp knife, by exerting slight traction on the upper end of the folded strip, the plaster shoe may be split.

The second foot is now done in the same way, during which time the first shoe is left in place. After the second has been cut, the first is removed carefully, the cut edges approximated, and the mold sealed by taking the strip which has just acted as a director on which to cut, spreading it out, wetting it and passing it longitudinally down the dorsum of the mold over the split and over the opening where the toes had been and back to the heel. This strip is long enough and has retained plaster enough to effectually seal the mold. The second is now likewise treated. Thus a light, inexpensive mold, the materials for which are easily transported, may be made easily and accurately, one which holds its shape and does not break if dropped.

The cast is made by mixing about 2½ cups of good dental plaster with 1½ cups of cold water, which, when well mixed, is poured in through the ankle opening. If the sealing strip has been started at the proper level (about 1 inch below the level of the malleoli) the mold will have a broad, flat base, which is preferred by the plate makers.

10 Exophthalmic Goiter. F. P. Sturm.

3. **Instrumental Labor in Colliery Practice.**—Crawford gives in this article a summarized report of 1,000 cases of labor, practically consecutive, in which instrumental interference was necessary. He had four deaths in the series; thirty craniotomies; two face presentations, both of the favorable type; one brow presentation, requiring craniotomy; twelve transverse presentations, three of which occurred consecutively in the same patient and one anencephalic monster requiring forceps, as what represented the head would not engage in the pelvis. In discussing the frequency with which instrumental interference

is indicated among this class of patients, he states that there are two curious opinions current among the older midwives: (1) that if you have to attend a patient who by reason of her occupation has been "chained to a chair" you always get a badly ruptured perineum; (2) that instruments are undoubtedly called for more often now than formerly. The last opinion is based on the assertion that the babies are larger now than formerly, and that the parents get better food and take life more easily than of old.

16. **Specificity of Cancer.**—Believing that "no disease more plainly bears on itself the impress of specificity than cancer," Brand is of the opinion that the successful attack on cancer can be made only by specific means. He maintains that as syphilis yields to internal specific treatment so will cancer when once the specific parasiticide or vaccine, as the case may be, for cancer has been discovered. He submits that the proper treatment of cancer will consist in the removal by surgical means of accessible tumors, especially those which threaten life from mechanical causes, combined with the internal administration of specific remedies—when discovered. The latter will be relied on to check the further spread of the disease and to neutralize that already existing by destroying the causal parasite. No less important, he believes, than the curative treatment of cancer is the prophylactic. This he considers to consist in cremation of cancerous cadavers, the destruction of all dressings from cancerous wounds, and of all discharges and dejecta from cancerous patients, preferably by fire; thorough disinfection of all rooms and houses inhabited by those suffering from, or who have died of, cancer; avoidance of intimate personal contact so far as possible and possibly total abstinence from all uncooked fruits and vegetables. Finally he would have enforced the notification of all cases of cancer.

20. **Syphilis in Light of Recent Research.**—Buschke concludes this postgraduate lecture with the statement that the most important element for the diagnosis and prognosis of syphilis is still as of yore careful clinical observation; the results of modern research have only made the foundation for this a little more solid. Treatment to date has not profited by recent research. Mercury and iodid are still the sole reliance in treatment of existing manifestations and their value in prophylaxis of tardy developments is still dubious.

24. **The Meiostagmin Reaction in Surgical Disease.**—This reaction was discussed recently in an editorial in The Journal, May 28, page 1790; d'Este here describes its application for differentiation of surgical tuberculosis, cancer, hydrocele, hernia, etc. He tabulates the details in about 35 cases, with the controls. They seem to show that this reaction can be counted on in the diagnosis of active tuberculous lesions but that it is not observed with merely latent processes. The findings were invariably positive in the cancer cases.

27. **Inflammatory Tumors at the Sigmoid Flexure.**—Arnsperger states that in these tumors operative treatment is indicated if for no other reason than that they simulate cancer so deceptively. He operated in a case of the kind on assumption of carcinoma of the sigmoid flexure, but the lesion proved to be merely a simple, chronic, inflammatory process in the subserous tissue leading to partial dissection of the layers of the bowel wall, with signs of a more acute process in the serosa, mucosa and muscularis. Another case of the kind came to autopsy. The lesions are distinguished by the sharp demarcation from sound tissue and their hard consistency with tendency to adhesions. The mucosa may remain intact and free from stenosis.

28. **Operations on the Nervous System.**—The history, the differentiation of the lesion, the operative findings and the complete recovery are analyzed both from the neurologic and surgical standpoints in the case of intradural fibroma reported. The fibroma was in the upper dorsal and lower cervical segments of the spinal cord and had caused paralysis of the legs, with some retention of urine and tonic spasms as violent as in tetanus. Intermittent neuralgic pains in the region of the tumor had been noted with increasing severity for six years but there was no local tenderness. The operation was done in two sittings with four days' interval; it was followed by flaccid paralysis for six weeks, but this gradually subsided and by the end of the year there was no trace of the former disturbances. The writers describe further their experiences with a glioma in the left half of the cerebellum of a girl of 12. As the operation was attempted there was profuse hemorrhage from an aneurism, and it was arrested only by plugging with wax a defect in the bone. Vomiting, Cheyne-Stokes breathing and stupor developed later and the patient succumbed in the course of eleven hours. It is possible that the loss of blood permitted the large tumor to press on the medulla oblongata, inducing the vomiting and abnormal breathing, the condition thus comparable to the mishaps after lumbar puncture in case of brain tumors. In another case reported, a neurofibroma was removed from the upper arm of a young man, leaving a defect 5 cm. long in the ulnar nerve, and yet there were no symptoms of impaired motor functioning afterward; collateral nerve routes must have developed during the gradual growth of the tumor.

29. **Pneumococcus Bursitis and Tendovaginitis.**—Kaumheimer reports four cases in which abscesses developed in the bursa of the shoulder and knee and, in one case, in the tendon sheaths of the wrist and ankle. The joint itself was not involved, and pneumococci were cultivated from the pus in each case. The patients were infants one and two years old; one giving a positive tuberculin skin reaction succumbed to measles not long after, the others promptly recovered. Kaum-

heimer was able to find on record only four similar cases of pure para-articular pneumococcus suppuration, and in each the bursa of shoulder or knee was the first affected, especially the subdeltoid bursa. There had been preceding pneumonia in only one of his cases, but there was a history of recent otitis media in another case.

31. **Congenital Megacolon.**—The features of the three cases described indicate that the trouble was the result of a congenital valve-like protrusion of the wall of the large intestine into the lumen, two such protrusions overlapping and closing the lumen completely at times. In 58 cases on record in which an operation was done only 25 of the patients survived, but the operation had generally been delayed until pronounced ileus had developed. In the cases reported, the autopsy or operative findings confirmed the above assumption of the cause of congenital megacolon.

32. **Chronic Intoxication from Abnormal Thyroid Functioning.**—Kostlivy has been conducting extensive research to ascertain whether the true and incomplete forms of exophthalmic goiter are different entities, and has examined 42 patients with thyroid disturbances, including 9 with pronounced exophthalmic goiter, recording the blood picture, the hemoglobin percentage, leucocytosis and coagulating time, dilatation of the pupil after instillation of epinephrin, also testing the blood serum for epinephrin content, with experimental work. His conclusions are that there seem to be two distinct types of chronic intoxication from perverted thyroid functioning, one depending on the sympathetic system and the other on the vagus system. In exophthalmic goiter the two types may be combined; the vagus type predominates during the remissions and the sympathetic type predominates during the exacerbations. The sympathetic hyperthyroidism is the primary, the vagus type being more of a secondary compensating process, but it may assume the preponderance in time. The morbid functioning of the thyroid which entails this modification in the tone of these antagonistic nerve systems may be the result of infectious or bacteriotoxic influences. There may be isolated patches in the thyroid in which the secretion is perverted while the balance may be sound; this assumption would explain the cases in which, after removal of part of the enlarged thyroid, severe acute symptoms of hyperthyroidism develop. The sound parts had been removed by the operation, leaving merely the islands of abnormally functioning tissue. Such cases have been reported by Kocher and others, and two of Kostlivy's cases were of this type, the acute postoperative exophthalmic goiter symptoms proving rapidly fatal. In 3 of his other cases a similar acute and severe postoperative predominance of the sympathetic element was observed but gradually subsided. In 4 others an acute postoperative predominance of the vagus element was unmistakable. The postoperative predominance of the vagus element is not so dangerous as that of the sympathetic; he advises abstention from surgical measures in all cases of exophthalmic goiter in which extreme lymphocytosis and slight epinephrinemia indicate that the thyrotoxic poisoning is the work of small patches of abnormal tissue in the gland while the main part of the thyroid is in a vagotropic compensating hypertrophy. Strumectomy in such a case is liable to be followed by serious acute Basedow symptoms, almost inevitably fatal. This assumption of a disturbance in the coördination of the vagus and sympathetic elements as the basis of the "thyrotoxicoses" suggests the possibility of successful serotherapy, giving a hypothyroidism serum or hyperthyroidism serum as indicated in the individual case. This individualized serotherapy might prove useful also as a supplement to operative treatment. In conclusion he urges not to restrict operative measures to the severest cases, and postpone them until after failure of all internal treatment. The incipient thyrotoxic disturbances are most amenable to surgical treatment and give the best results as the primarily affected parts are removed before they have had a chance to do irreparable damage. Later than this, the outlook is far less encouraging on account of the changes induced by compensating processes not only in the thyroid itself but in the other ductless glands coordinated with the thyroid or antagonistic to it.

38 *Typhoid Bacillus-Carriers. (Tyfusbacilbærerne.) T. Madsen.
39 Tuberculin in Treatment of Pulmonary Tuberculosis. (Nogle Resultater af Tuberkulinbehandling ved Lungetuberkulose.) E. R. Schneider. Commenced in No. 13.

38. **Typhoid Bacillus Carriers.**—Madsen emphasizes the importance of keeping typhoid patients in the hospital until they are entirely free from bacilli. He adds that if they could be reexamined six or twelve months afterward, especially the adult women patients, much would be gained. If bacilli are discovered, the carrier should be instructed in prophylactic measures but with great care not to inform others of the positive findings, as most serious results may follow the knowledge in the environment. Only when the carrier refuses to submit to prophylactic measures should more drastic steps be taken. He urges search for the source of infection in every case of typhoid fever, and that the district physician should be informed when a known carrier is in his jurisdiction, so that he can keep him under supervision. The carriers that have proved most dangerous are women engaged in household work. In one such case recently, the mistress of the house in the course of years had infected a number of persons in turn, mainly newly arrived servants.

A Manual of Midwifery. For Students and Practitioners. By Henry Jellett, M.D., King's Professor of Midwifery in the School of Physic, Trinity College, Dublin. With the Assistance in Special Subjects of W. R. Dawson, M.D., H. C. Drury, M.D., T. G. Moorhead, M.D., and R. J. Rowlette, M.D. Second Edition. Cloth. Price, $6 net. Pp. 1210, with 557 illustrations. New York: William Wood & Co., 1910.

Diseases of Infancy and Childhood: Their Dietetic, Hygienic and Medical Treatment. A Text-Book Designed for Practitioners and Students in Medicine. By Louis Fischer, M.D., Attending Physician to the Willard Parker and Riverside Hospitals of New York City. Third Edition. Cloth. Price, $6.50 net. Pp. 980, with 303 illustrations. Philadelphia. F. A. Davis Company, 1910.

Essentials of Laboratory Diagnosis. Designed for Students and Practitioners. By Francis Ashley Faught, M.D., Director of the Laboratory of the Department of Clinical Medicine, Medico-Chirurgical College, Philadelphia. Second Edition. Cloth. Price, $2 net. Pp. 336, with illustrations. Philadelphia: F. A. Davis Company, 1910.

Handbook of Anatomy. Being a Complete Compend of Anatomy, Including the Anatomy of the Viscera and Numerous Tables. By James K. Young, M.D., Professor of Orthopedic Surgery, Philadelphia Polyclinic. Third Edition. Cloth. Price, $1.75 net. Pp. 402, with 172 illustrations. Philadelphia: F. A. Davis Company, 1909.

Hygiene and Morality. A Manual for Nurses and Others, Giving an Outline of the Medical, Social and Legal Aspects of the Venereal Diseases. By Lavinia L. Dock, R.N., Graduate of Bellevue Hospital Training School. Cloth. Price, $1.25 net. Pp. 200. New York: G. P. Putnam's Sons, 1910.

Introduction to the Analysis of Drugs and Medicines. An Elementary Handbook for the Beginner. By Burt E. Nelson, Chemist to the New York State Hospitals. First Edition. Cloth. Price, $3 net. Pp. 384, with 31 illustrations. New York: John Wiley & Sons, 1910.

Age Incidence, Sex, and Comparative Frequency in Disease. By James Grant Andrew, Bachelor of Medicine and Master of Surgery. Cloth. Price, $4.20 net. Pp. 430. New York: Paul B. Hoeber, 69 E. 59th St., 1909.

GENERAL INDEX

All *reading matter* in The Journal from January to June, 1910, inclusive, is indexed here. (For Current Medical Literature Index see pages 2174 to 2228). "Deaths," "Book Notices" and "Society Proceedings" are indexed under those titles at the ends of the letters "D," "B" and "S." Matter pertaining to the Association is under "American Medical Association." With the above exceptions, all matter is indexed under the most important word of the heading that was used in The Journal, and also under the subject heading. For instance, "abscess of brain" will be found indexed under "abscess" as well as under "brain." Such titles as "ocular manifestations, etc.," have been indexed under "eye." Cross references have been made wherever this was possible. It is well to remember that, in looking up a certain subject, related words should be consulted, for example, testes, testicle; skull, cranium; bowel, intestines. The letters used to explain in which department the matter indexed appeared are as follows: "E" editorial; "O" original article; "C" correspondence; and "ab" denotes an abstract of an article that has appeared in full elsewhere. *Names of Authors* of original articles appearing in The Journal are not given in this index, but are included in the Index of Authors.

  fistulas, therapeutic possibilities of, 1—O
  tract infection, 1892—ab
Biographical data, medical, wanted, 1803—C
Biology problems, application of immunology to, 973—E
Birth, hour of, 1407—ab
Birth-rate among Jews and Christians, 1322
  and infant mortality in Prussia, 479
  diminishing, in Great Britain, 301, 2054
  lowest, on record, 803
  low, in Scotland, 1703
Bismuth beta-naphtholate-correction, 220
  new studies of, 1659—ab
  paste in tuberculosis of ossacrum, 701—O
  subnitrate gauze for use in nose, 252—O

- Black list, proposed, for mishaps from new drugs and measures, 1014—ab
- Bladder and kidney surgery, 663—ab
  - calculi, symptoms of, 1765—ab
  - calculus in, encysted, with pedicle, 127—O
  - double ureteral implantation into, case of, 1408—ab
  - hypertrophy of trabeculæ in, early sign of tabes dorsalis, 751—ab
  - large iodoform-gauze tampon in, for 10 months, 742—ab
  - necrosis of, with exfoliation, 1903-ab
  - neoplasms, removal of, 1768—O
  - operations, prevention of bleeding in, 1309—O
  - partial resection of, for malignant tumor by transperitoneal route, 238—ab
  - removal of, for carcinoma, 1912—ab
  - rupture of, operated on 77 hours after injury, 1207—O
  - symptoms and extra-bladder pathology, 1401—ab
  - technic for surgical hemostasis in, 2102—ab
  - to hasten healing of fistulas into, 1017—ab
  - tumor, unusual type of, 151—ab
  - tumors of, 1573—ab
- Blastomycosis with epithelioma of jaw, 399—ab
- Blennorrhea neonatorum, cause, prevalence and prophylaxis, 1409—ab
- Blind, association for benefit of, 1557
  - compensating acuteness of senses of, 541—E
  - conference for welfare of, 1703
- Blindness, Color: See Color Blindness
- Blindness due to *ophthalmia neonatorum*, 322—ab
  - *from* adulteration of medicine with wood alcohol, 86—ab
  - from heroin in nostrum habitina, 869—O
  - preventable, 1992—ab
  - prevention *of*, 1814—ab
  - prevention of, general professional responsibilities for, 1638—ab
  - sun, 1015—ab
  - unnecessary, 739—ab, 1143—ab, 1992—ab
  - what has been done against increase of, and what can be done, 1816—ab
- Blood and sputum, examination of, in *tuberculosis*, 570—ab
  - aspirator, 1690—O
  - bacteriology of, in surgical affections, 87—ab
  - cells, red, human, subcutaneous injection of, skin reaction from, in carcinoma, 819—ab
  - cells, red, relation of catalytic activity to number of, and to number of white blood cells and body temperature in peritonitis, 413—ab
  - cells, white, and body temperature in peritonitis, relation of catalytic activity of blood to number of red blood cells in health, and to number of, 413—ab
  - coagulating power of, determination of, 1584—ab, 1892—ab
  - coagulation of, during menstruation, 1096—ab
  - count, differential, simplified technic for, 663—ab
  - counting pipettes, stopper for, 467-O
  - cultures, early diagnosis of typhoid by, 756—O, 1650—ab
  - detection of tubercle bacilli in, by Rosenberger's method, 739—ab
  - diagnosis of lead poisoning, 167—ab
  - effect of experimental, long-continued small doses of quinin on, 1732—ab
  - examinations for hemameba of malaria, 1808—ab
  - films, dried, labeling of, 125—O
  - *findings in animals* long given small doses of quinin, 1420—ab
  - *findings* with abnormal spleen, 1097—ab
  - formation of antibodies by, 1089—ab
  - flow, venous, changes in, on administration of amyl nitrite, 1901—ab
  - formation of antibodies by, and their distribution, 130—O
  - general syndromes in pathology of, 1583—ab
  - [illegible] of, 1997-ab
  - in [illegible] 1014—ab
  - in [illegible]
  - in [illegible]
  - in 20 cases of pellagra in insane asylum of Louisiana, 1337—ab
  - influence of various organs on catalytic activity of, 1237—ab
  - lepra bacillus in, 1726—ab
  - means of reducing operative loss of, 421—ab
  - menstrual changes in, 1096—ab
  - normal and pathologic, hemagglutinins, hemopsonins and hemolysins in, 1562—ab
- Blood, occult, in feces, benzidin and guaiac tests for, 422—ab
  - of typhoid patients, isolation of bacillus typhosus from, 1648—ab
  - picture suggestive of pernicious anemia and gastric cancer with metastases *in bone marrow*, *1827*—ab
  - picture, unusual, recurrent furunculosis *in infant showing*, 1854—O
  - producing organs, and rachitis, 86—ab
  - production, *importance* of reduced oxygen tension of tissues as stimulus to, 86—ab
  - *relation of catalytic activity* of, to number of red blood cells in health, and to number of white blood cells and body temperature in *peritonitis*, 413—ab
  - serum, *syphilitic*, changes in drop-*forming property* in, meiostagmin *reaction*, 827—ab
  - sexual forms of malarial plasmodia in, 1725—ab
  - spitting or coughing of, and serious *illness*, 77
  - spots, medicolegal *study*, 1338—ab
  - tests, biologic, differentiation between *dementia* præcox and depressive states by, 1868—O
  - transfusion, direct, 5 cases *of*, 2101—ab
  - transfusion, direct, *indications* for, 1824—ab
  - transfusion, *peritoneal*, 1173—ab
  - trichinella spiralis in, 1297—O
  - tubercle bacilli *in*, 137—*E*, 322—*ab*
  - tubercle bacilli in, detection of, 739—ab
  - vessel and organic heart disease, relations between disturbances in innervation and, 1914—ab
  - vessels, closure of, after delivery, 824—ab
  - vessels, functional adaptability of walls of, to new blood-pressures, 1545—ab
  - vessels, influencing *pulse* by *external pressure* on, *1730*—ab
  - vessels of neck, rupture of, into pharynx in scarlet fever, 657—ab
  - vessels, peripheral, importance of functioning of, with failing compensation, 1347—ab
  - vessels, renal, abnormal, and their connection with *hydronephrosis*, *499*—ab
  - vessels, surgery of, 659—ab, 824—ab
  - vessels, suture of, with human hair, 349—O
  - vessels, *transplantation of*, 1415—ab
  - vessels, transplanted, histology of, 1545—ab
  - viscosity *of*, 378—E
- *Blood-pressure*, apparatus for estimation of, *1136*—*O*
  - edema of lungs with paroxysmal increase *in*, 1241—ab
  - higher, experimental chronic nephritis entailing, 1486—ab
  - in epidemic cerebrospinal meningitis, 2097—ab
  - in superficial veins, method for determination of, 1345—ab
  - in toxemias of pregnancy, 1647—ab, 2139—ab
  - new, *functional* adaptability *of* walls of blood-vessels to, 1545—ab
  - occurrence of acute edema of lung with paroxysmal increase in, 500—ab
  - past middle life in diagnosis, prognosis and *treatment*, *409*—*ab*
  - reduction of, 1666—O
- Blotting-paper mold for obtaining crayons of carbonic-acid ice, 1519—O
- Body, animal, influence of regenerating tissue on, 399—ab
  - fluids of normal and immune animals, study of concentration of antibodies in, 494—ab, 568—ab
  - living, effects of injections of killed streptococci in, 1892—ab
  - orifices, diseases of, 571—ab
  - physical development of, and school houses and school habits, 2096—ab
  - temperature and number of white blood cells in peritonitis, relation of catalytic activity of blood to red blood cells in health and to, 413—ab
- Bolus alba, 808
- Bone autoplastic operation to close defects in skull, 748—ab
  - deformity, constitutional diseases of *infancy cause* of, 1410—ab
  - fish, *death from* septicemia after removal of, from rectum, 1577
  - forceps, submucous, anterior, 1614-O
  - *formation in penis* and its successful removal, 502—ab
  - grafting, intrahuman, and reimplantation *of bone*, 237—ab
- Bone growth, normal, action of thyroid extract *on*, 824—ab
  - holding forceps, 459—O
  - long, plastic operation after resection of, 1833—ab
  - marrow, gastric cancer with *metastases in*, and blood picture suggestive of pernicious anemia, 1827—ab
  - reimplantation of, and intrahuman bone grafting, 237—ab
  - suppurative, and joint disease, therapy by bacterins and tuberculins in, 647—ab
  - *tumors, primary, malignant*, 240—ab
- Bones, long, *in children*, linear and subperiosteal fractures of, 1204—O
  - long, methods of treating large cavities in, 1660—ab
  - long, plea for conservative *treatment* of sarcoma of, 333—O
  - tuberculosis of, 731—ab
  - vascular tumors and aneurisms in, 914—ab
- Botryomycosis in man, case of, 657—ab
- Bouchard, retirement of, 478
- Boy of four, dermoid cyst, *accompanied* by appendicitis in abdomen of, *460*—O
- Boys *and girls*, comparison of weight, height, epiphyseal development in, 1889—ab
  - cystoscopic diagnosis of tuberculosis of kidney in, 660—ab
- Bracelet, metal, *for fixation of* stumps *after fracture of radius*, 1413—ab
- *Braces, advantages of*, over plaster *jackets in* Pott's disease, 1995—ab
- Brachialis anticus, osteoma of, 1413—ab
- Brain arteriosclerosis, symptomatology *of*, 920—ab
  - central flap in exposure of, 941—O
  - changes, importance of Schwabach's *test for diagnosis* of, 1346—ab
  - concussion of, 573—ab
  - concussion of, material bases for and *prognosis of traumatic* neuroses *after*, *1831*—ab
  - *cortex*, circumscribed motor paralysis and cutaneous anesthesia following *injury* of, 1646—ab
  - *cortex*, circumscribed serous meningitis of, *326*—ab
  - dermoid cysts of, 1728—ab
  - disorders, influence of *intercurrent infections* on, 469—ab
  - gunshot wound *of*, without *focal* symptoms, 239—ab
  - hemorrhages, distribution of, 239-ab
  - injuries of, diagnosis and treatment of, 1584—ab
  - lesions and skull, x-ray diagnosis of, 573—ab
  - lesions complicating ear *diseases*, eye symptoms with, 320—ab
  - lesions, increasing mortality in United States from, 1159—ab
  - lesions with eye symptoms cause of ear disease, 409—ab
  - localization, based on clinicopathologic study of mental disease, 1482—ab
  - overhanging, exposed, research on, 1243—ab
  - physiology of, points from operative experience, 659—ab
  - pressure, puncture of corpus callosum to reduce, 246—ab
  - pseudotumors of, and serous meningitis in ventricles, 1343—ab
  - storm, 1084—ab
  - *structures concerned in vision*, 241-ab
  - surgery, 167—ab
  - surgery, aspect of, based on therapeutic significance of acute and chronic intracranial hypertension, 80—ab
  - surgery, differential pressure procedure for inducing anemia in, 90—ab, 421—ab
  - syndrome, from hypertension of cerebral fluid, 1484—ab
  - *syphilis*, *1504*—*O*, *1992*—ab
  - transplantation of spinal ganglion into, 654—ab
  - tumor, symptomatology and localization of, 579—O
  - tumors, symptomatology and treatment of, 1345—ab
- Brandy and whisky omitted from Pharmacopeia, 891—C
- Bread, kneading of, by machinery, in France, 62
- Breakfast foods, Connecticut report on, 1558
- Breast, autoplastic *amputation* of, 829—ab
  - cancer of, radical operation for, 178—O
  - carcinoma of, *100 operations for*, 497—ab
  - carcinoma of, x-ray in, 161—ab
  - nursing, premiums for, 387
- Breast pang, 1173—ab
  - tuberculosis plus adenocarcinoma of, 1415—ab
- Breathing, diaphragmatic, with weakness and insufficiency of heart, importance of, 1656—ab
- British army, health of, in 1908, 60
  - Medical Journal, damages *for* libel recovered from, *547*
- Bromin-iodin compound, 1884
- Bromo febrin, 984
- Bronchial disease, new sputum test for distinction of, from pulmonary disease, 470—E
  - Vincent's angina, 1867—O
- Bronchitis, chronic, persistent, in children, 1907—ab
  - chronic, treatment of, 79—ab
- Bronchopneumonia, epidemic, influ*enza bacillus* as cause of, 82—ab
  - in children, systematic oxygen treatment of, 747—ab
- Bronchopulmonary disease, acute, fixation abscess in, 915—ab
- Brudzinski's neck sign and contralat*eral reflex*, *value of*, in diagnosis of meningitis in infancy and childhood, 1712—ab
- Bulletin, publication of, by *county* society, 899—O
- Bundle-of-His, relation of digitalis *to*, 1648—ab
- Buphthalmia or infantile *glaucoma*, 1173—ab
- Burn, which involved one-half body area, 78—ab
- Burns, 162—ab
  - dressing for, 820—ab
  - electric, 506—O
  - management of, 908—ab
- Burow's solution, fatal lead poisoning from use of, 1056—O
- Bursitis and *tendovaginitis*, pneumococcus, purulent, in young children, 2141—ab
- Bye, W. O., cancer cure declared fraudulent, 481

  intestinal, from horse, cow and man, comparative study of, 567-ab
  killed, effects of injections of, in living body, 1892—ab
  new color medium for isolation and differentiation of, 568—ab
  Streptococcus and B. coli vaccine, uses of, in urinary diseases, 1007-ab
  and pyogenic infection in sarcoma, 1303—O
  infection and leucocytosis, 660—ab
  mucosus capsulatus, causing chronic suppurative parotitis, 47—O
  serum, 286
  staphylococcus, and pneumococcus infections, investigations of serums and vaccines for, 257—O
  vaccine, 288
  vaccine, scarlet fever prophylaxis with, 907—ab
Streptotrichoses and tuberculosis, 1089—ab, 1171—ab, 1340—ab
Strophanthin, 1050—O
Strychnin and novocain, death from intraspinal injection of, 1341—ab
  new studies of, 1659—ab
  poisoning, 1612—O
Students, German, increase of, 387
Stumps after fracture of radius, metal bracelet for fixation of, 1413—ab
Stuttering, congenital word blindness with, 818—ab
Succussion and taxis, new treatment for intussusception, 1010—ab
Sugar and rice as transmitters of cholera, 1326—C
  laboratory manufacture of, from protein and fats, 391
Suggestion, mainspring of hypnotism and psychotherapy, 738—ab
Sun-blindness, 1015—ab
Suicide by hypodermic injection of potassium cyanid, 1556
  pathologic anatomy of, 1659—ab
Suports and orthopedic corsets, 325—ab
Suppuration and inflammation of omentum, 323—ab
  in knee-joint, causes and treatment, 914—ab
  in lungs and pulmonary tuberculosis, difficulty of differentiating between, 1583—ab
  of uterine fibroid, 1237—ab
Suppurations, bone, 740—ab
  serotherapy of, 1095—ab
Suppurative complications of contagious diseases, injections of homologous streptococci killed by galactose in, 568—ab
Suprarenal, engrafted, survival of, 832—O
  preparations, commercial, activity of, 710—E
  transplantation in Addison's disease, 652—ab
  treatment of osteomalacia, 165—ab
  tumor with punctate pigmentation, 1017—ab
Suprarenals, absence of, 565—ab
  hemorrhage in, due to chloroform, 1828—ab
  hypoglycemia in dogs after removal of, 662—ab
  phenomena after experimental removal of, 421—ab
Sure thing tonic, 1626
Surgeon, practitioner, and medical education, 2137—ab
Surgeon-General, new, 546
Surgeon-General's Library, borrowing periodicals from, 809
Surgeons and physicians, American, Congress of, 1635—ab
  army, history of Munich surgical institute for, 1346—ab
  part of, in treatment and prevention of criminals and defectives, 1634—ab
Surgery, abdominal, in America, early history of, 600—O
  American, an appreciation, 2049—E
  and general therapeutics in dentistry, 608—O
  and medicine, don'ts in, 1815—ab
  and medicine, proposed section on physical forces in, 1460—C
  antiseptic, modern, 1104—O
  balsam-oil dressing in, 1235—ab
  blood in, 566—ab
  casualty, normal saline solution as dressing in, 1480—ab
  conservative, in eye injuries, 1480-ab
  elements of success in, 492—ab
  experimental, aims and tasks of, 166—ab
  for neurasthenic conditions with visceral ptoses, end-results of, 1715-ab
  gutta-percha tissue in, 1325—C
  major, nitrous oxid and oxygen in, 1422—O
Surgery, modern, tendency of, 1006-ab
  nitrous oxid in, 1422—O, 1589—O
  of joints, 2138—ab
  of renal calculi, progress in, 647—ab
  of thoracic aorta, exprimental, by method of Meltzer and Auer, 28—O, 1584—ab
  operative, two-stage principle in, 566—ab
  original contributions to, 1297—O
  uses of catgut in, 324—ab
Surgical celerity, value of, 1006—ab
  junk, demanding surgical interference, 70—ab, 569—ab
  society, German, annual meeting of, 1455
Suture, intestinal, 315—ab
  material, unabsorbable, or catgut? 576—ab
  new, double figure-of-eight, 1500—O
  tendon, reliable, 1371—O
Sutures, human hair as, 631—C
  unpedunculated flaps to insure healing of, 825—ab
Sweats in tuberculosis, efficacy of camphoric acid in, 1420—ab
Sykes, J., and a cholera epidemic, 1072—C
Symphysis, rupture of, during delivery, 1832—ab
Syphilids, cutaneous, proliferating forms of, 18—O
Syphilis, acquired, in hereditary syphilitic, 739—ab
  adequacy of present treatment of, tested by syphilitic nervous diseases, 731—ab
  adult, of lung, 492—ab
  and American negro, 846—O
  and idiocy, 169—ab
  and insanity, 1073—ab
  and paresis, 1064—E
  aortitis due to, with aortic insufficiency, 118—O
  brain, 1992—ab
  cerebral, 1504—O
  cerebrospinal fluid in, 699—ab
  cerebrospinal, protracted, with striking intermittency of symptoms, 1476—ab
  complement fixation in, simple method of, 656—ab
  congenital, in foundling asylums, diagnosis of, 1660—ab
  congenital, late, syphilis of liver probably case of, 1053—O
  congenital, of heart, 1807—ab
  congenital, recent observations on, 878—E
  congenital, spasmodic paraplegia in children with, 1175—ab
  diagnosis and treatment of, 2141-ab
  diagnosis of, by staining reaction, 1098—ab
  diseases of nervous system due to, 1349—O
  early jaundice due to, 1093—ab
  endarteritis in, gangrene from, 817-ab
  immunization against, by other venereal disease, 551—C
  importance of spirochetes for clinical diagnosis of, and India ink preparations, 918—ab
  in aortic insufficiency, seroreaction for, 830—ab
  inheritance of, 1418—ab
  injections in, 1320
  late, luetic lymphoma in, 605—O
  latent, diagnosed by Wassermann reaction, 1650—ab
  long incubation periods of, 654—ab
  malformations due to, 1728—ab
  mediate contagion of, and prophylaxis, 1346—ab
  mercury in, 1692—ab
  of liver, probably late congenital syphilis, 1053—O
  of nose, operative correction of, 1085—ab
  of thyroid, 652—ab
  potassium chlorate in serodiagnosis of, 329—ab
  quinin in, 244—ab
  relapses in, due to tonsils, 681—ab
  serodiagnosis of, 89—ab, 170—ab, 924—O, 1114—O, 1729—ab, 1808—ab
  serodiagnosis of, with autopsy control, 246—ab
  serum and precipitate reactions for, clinical value of, 1114—O
  spirochæta pallida in relation to, 924—O
  technic and value of Wassermann reaction in diagnosis and treatment of, 1808—ab
  treatment of, comparative value of various methods of, 1906—ab
  treatment of, in light of latest research, 748—ab
  visceral, manifold manifestations of, 2008—ab
  tuberculin tests in, positive, 1840-ab
Syphilitics, tuberculin reaction in, 1484—ab
  who have become tabetic, absence of iritis and chorioiditis among, 933—O

Syringe for treatment of certain vaginal diseases, 2042—O
Syringomyelia, spasmodic, 571—ab
  unusual type of, 239—ab
Systemic diseases and diseases of mouth, relations between, 1007-ab

  of skin of fingers in health and disease, 1660—ab
  perception, abnormal, 1486—ab
  reaction, topical, in pulmonary tuberculosis, 1244—ab
  subfebrile, in diagnosis and treatment of pulmonary tuberculosis, 1656—ab
  variations of, in pulmonary tuberculosis during menstrual period, 1172—ab
Tenaculum, tonsil, spiral, new, 1372-O
Tendon Achilles, substitution of muscle for, 496—ab
  suture, reliable, 1371—O
  transplantation in flat-foot, 1726—ab
  transplantation, technic and results of, for quadriceps paralysis, 328-ab
Tendovaginitis and bursitis, pneumococcus, purulent, in young children, 2141—ab
Tennessee medical news, 623, 884, 977, 1217, 1452, 1701, 1797
  state board May report, 562
Teratoma of the testicle and its derivatives, two rare cases of, 228-ab
Test: See also Tests
Test, bead, of Einhorn and test diet for intestinal diseases of Adolf Schmidt, 1405—ab
  colorimetric, for salicylic acid, 635
  electric, for traumatic neurosis, 243—ab
  for estimation of pepsin, 168—ab
  hemolytic, in cancer and tuberculosis, diagnostic value of, 1057—ab, 2097—ab
Test, indigo-carmin, of kidney functioning, practical importance of, 1094—ab
  meal removal, improved apparatus for, 1007—ab
  Schwabach's, importance of, for diagnosis of intracranial changes, 1346—ab
  silver carbonate, for uricacidemia, 1005
  glycyl-tryptophan, for carcinoma of stomach, 2095—ab
Testicle, cancer of, clinical diagnosis of, 2099—ab
  chorieoepithelioma of, 1340—ab
  lymphatics of, 1011—ab
  teratoma of, and derivatives, two rare cases of, 228—ab
  undescended, value of, 498—ab
Testicles and glands, lymphosarcoma of, 1091—ab
  transplantation of, 1342—ab
Testimony as to statements by patients, admissibility in evidence of, 1900
  expert, on insanity, intoxication and epilepsy as defenses to crime, 564
  expert, required against malpractice by corporation and unlicensed person, 1404
  medical expert, 236—ab, 993—ab
Tests: See also Test
Tests, benzidin and guaiac, for occult blood in feces, 422—ab
  nystagmus, labyrinthine, clinical value of, 242—ab
  phloridzin, of kidney functioning, 1015—ab
Tetanus and Fourth of July are coming, 1947—E
  antitetanic serum in, 1075—ab
  antitoxin, 287, 1958
  antitoxin and vaccine virus, committee of Section on Pathology and Physiology recommends their admission to Pharmacopeia, 1389
  antitoxin, commercial preparations of, 253—O
  antitoxin, death of injured hay-fever patient right after administration of, 2094
  antitoxin, prophylactic use of, 533-O
  antitoxin, value of, 1803
  baccilli, dissemination of, 470—E
  developing twelve days after shortening of round ligaments, recovery, 108—O
  hysterical, 1442—O
  serotherapy of, 533—O, 1731—ab, 1830—ab
  treated with subcutaneous injections of magnesium sulphate, recovery, 1482—ab
  with point of infection cavity of tooth, 817—ab
Tetany in rabbits, 88—ab
  leg, sign of, 1244—ab
  postoperative, acute, organotherapy of, 1912—ab
Texas law explained in regard to illegal practice of medicine by masseur doctor, 1900
  medical news, 299, 624, 1217, 1318, 1555, 1701, 1797
  medical practice act, legal status of, 639—ab
  state board November report, 489
Thalamic syndrome, 817—ab
Thallium salts, toxicity of, 570—ab
Therapeutic recommendations, careful, 535
Therapeutics and materia medica, practical methods in teaching of, 228—ab
  general, and surgery in dentistry, 608—O
  has it kept pace with advance of other branches of medical science? 1904—ab
  local, importance of chloral for, and for pathologic-anatomic research, 170—ab
  progress of, 1809—ab
Thermopenetration, 2101—ab
Thesis requirement, reform of, for doctorate degree in France, 386
Thigh, fracture of, in new-born, 1325
Thiol, 1208
Thiolum, 1208
Thirst fever in infants, 1729—ab
Thoracostomy, precordial, 41—ab
Thorax, anterior, lines to aid in topography of, 1345—ab
  clinical significance of silent fluids in, 1465—ab
  empyema of, surgical treatment of, 567—ab
  rigid, indicating chondrotomy, causes and effects of, 1585—ab
  surgery of, efficiency of positive pressure method in, 1088—ab
  surgery of, experimental, by method of Meltzer and Auer, 28—O
  surgery of, paramount requirement in, 1166—ab
  surgery of, in differential pressure procedures in, 169—ab
Thorax, surgery of, nitrous oxid and oxygen to maintain anesthesia and positive pressure for, 568—ab
Thoughts and emotions, influence of, in causation of disease, 413—ab
Threadworms, appendicitis due to, 48—O
Throat symptoms in diabetes, 1046—O
Thromboangiitis obliterans, is it related to Raynaud's disease and erythromelalgia? 493—ab
Thromboembolism, postoperative, 1344—ab
Thrombophlebitis of orbit, 752—ab
Thrombosis and embolism and allowing patients to get up early after operation or delivery, 87—ab
  clinical importance of, and present status of surgical treatment, 330-ab
  experimental research on, 87—ab
  in typhoid, prevention of, 420—ab
  of left iliac vein, 651—ab
  venous, and embolism of pulmonary artery, 87—ab
Thrush, 496—ab
  sporotrichosis and actinomycosis, agglutination and seroreaction in, 1174—ab
Thuja oil in corneal opacities, 2134
Thymectomy, technic and results of, 1655—ab
Thymol in uncinariasis, 2057
Thymus, desiccated, 1789
  enlargement of, clinical signs of, 1655—ab
  mediastinal tumor arising from, 1639—ab
  normal and pathologic histology of, 912—ab
  treatment of certain diseases, 816—ab
Thyreopriva tetany, transplantation of parathyroid in, 1415—ab
Thyroid and thyroidism, relation of, to toxemia of pregnancy, 158—ab
  carcinoma, epidemic of, among fish, 228—ab
  changes, diseases with, 66—ab
  engrafted, survival of, 832—O
  enlargements, significance of, 1724-ab
  extract, action of, on normal bone growth, 824—ab
  functioning, perverted, chronic intoxication from, clinical and experimental research on, 2142—ab
  in cretins, 351—ab
  internal secretion of, 1481—ab
  minute structure of, 1727—ab
  morbid susceptibility of, for iodin in certain families, 1347—ab
  primary bilateral ligation of upper poles of, for Graves' disease, 817-ab
  struction, distribution and variation of, in fish, 227—ab
  syphilis of, 652—ab
  treatment in epilepsy, 1912—ab
  treatment in infantile wasting, results of, 1826—ab
  treatment of regularly intermittent joint effusions, 1788—ab
  vessels, ligation of, in certain cases of hyperthroidism, 238—ab, 817—ab
Thyroidectomy, 1011—ab
  complete, ammonia-destroying power of liver after, 1238—ab
Thyroidism and thyroid, relation of, to toxemia of pregnancy, 158—ab
Thyroiditis, acute, and cardiovascular complications, 2007—ab
  acute, in puerperal infection, 1174-ab
Tic-douloureux, cerebello-pontile tumor diagnosed for six years as, 1600—O
  neurectomy of superior and inferior maxillary nerves for, 41—O
Tic of tongue, 312—ab
Tinkling, metallic, in hydropneumothorax, 1087—ab
Tinnitus and persistent vertigo, division of auditory nerve for, 315—ab
  entotic, in pregnancy, 969—O
Tissue, engrafted, survival of, 1901—ab
  normal, transplanted, capable of growth and transplanted tumor, comparison of, 1902—ab
  regenerating, influence of, on animal body, 399—ab
Tissues, engrafted, survival of, 832—O
  human, occurrence of lipase in, and its variation in disease, 912—ab
Toe, Hammer: See Hammer-Toe
Toe, overlapping, method for relief of, 1015—ab
Tongue, carcinoma of, 1313—E
  fixer and mouth gag for tonsil operation, 1136—O
  hairy, 1959
  in child, neurofibromatosis of, 823-ab
  tic of, 312—ab
Tonsil operation, combined mouth gag and tongue fixer and suction apparatus for, 1136—O
  physiology of, 987
  relation of spirochæta pallida to, 1597—O
  snare, simple, 1442—O
  tenaculum, spiral, new, 1372—O

Tonsillectomy in rheumatism and other infections, 1016—ab
Tonsillotome, new, 705—O, 1412 -O, 1942—O
Tonsils and adenoids, truth about, 1599—O
  cause of relapses in syphilis, 681—ab
  enlarged, practical method of anesthesia for removal of, 1724—ab
  faucial, chronic diseases of, 158—ab
  faucial, effect of removal of, on voice and reproductive powers, 147
  faucial, indications for removal of, and technic, 1819—ab
Tooth extraction, death under anesthesia for, attributed to status lymphaticus, 1320
  tetanus, with point of infection the cavity of, 817—ab
Toxemia of pregnancy and pathology of eclampsia, 653—ab
  of pregnancy, and relation of thyroid and thyroidism to, 159—ab
  of pregnancy, treatment of, 566—ab
  tuberculous, in surgery, 320—ab, 568—ab
Toxemias, gastroenteric, of bottle-fed infants in summer, prophylaxis and treatment of, 1125—O
  of pregnancy, blood pressure in, 1647—ab, 2139—ab
  of pregnancy, incidence and clinical causes of, 1649—ab
  pregnancy, etiology and pathology of, 566—ab
Toxicity of arsacetin, 1559
  of soamin, 1323
  of thallium salts, 570—ab
Toxins, prodigiosus, and erysipelas, 290
  results of federal control of manufacture of, 655—ab
Toxo-absorbent company, 550
Trachelorrhaphy, improved method of, 1202—O
Tracheobronchial catarrh, abdominal massage in, 1242—ab
Tracheotomy, transverse, 1016—ab
Trachoma, 1555
  bodies in conjunctival and genital secretions, 1729—ab
  bodies, possibly etiologic factor of trachoma, 160—ab
  cultivation of new bacillus in, 965—O

Zuckerkandl, death of, 2133

CURRENT MEDICAL LITERATURE

INDEX OF SUBJECTS

Explanation: This index refers to the titles and the subjects of original articles published in the leading medical journals of the world, including The Journal, during the past six months. The reading matter which appeared in The Journal is not indexed here, except the original articles and the abstracts of original articles. The titles of the articles and the names of the journals in which they appeared were listed weekly in the Department of Current Medical Literature, and it is to them that references are here made. The figure in parenthesis refers to the paragraph; the number following, to the page in The Journal. For instance, "Acne bacillus, (11) 78—ab," refers to page 78 of The Journal, on which is found, in paragraph numbered 11, the title of the paper and the name of the author, viz., "Bacillus of Acne, H. F. Hartwell and E. C. Streeter." This title is listed under the journal in which the article appeared, the *Boston Medical and Surgical Journal*, Dec. 16, 1909. When "ab" follows a page number it indicates that the article was abstracted in The Journal; for instance, "Abdominal cavity, pus in, (92) 1581—ab." On page 1581, paragraph 92, will be found an abstract of this article, which appeared in *Annals of Surgery*, April, 1910. Titles of articles which appeared originally in The Journal are indicated in the index by an asterisk (*) before the page number; for instance, "Abdominal drain, new, *1499," refers to page 1499 of The Journal, on which is found the complete original article. The index *to authors* of all articles, both original and those listed under Current Medical Literature, appears separately on pages 2229 to 2244 of this index.

A

Abdomen, examination of, facilitation of, (103) 88—ab
  false cancers and inflammatory tumors in, (52) 84—ab
  hyperesthesia of, and sympathetic aches, (75) 1829
  importance of early and complete operation in infectious and hemorrhagic conditions of, (150) 912
  indications for immediately opening, in acute cases, (1) 324—ab
  lower, intraperitoneal abscess in, proper treatment of, *2105
  position of patient after operations on, (20) 414
  removal of skin from, for skin grafting during laparotomy, (104) 911—ab
  upper, disease of, early symptoms of *357
  upper, diseases of, diagnosis and treatment of, (129) 163 (11) 497—ab
  upper, diagnosis and treatment of peritonitis of, (9) 1475—ab
Abdominal and pelvic surgery, methods of drainage in, (108) 495
  cancers and tumors, diagnosis of, antitrypsin test and casein reaction, (159) 421
  carcinoma, hopeless, pelvic transplantation metastasis as means of recognition of, (89) 911
  cavity, echinococcus of multiple, (130) 1911
  cavity, pus in, (92) 1581—ab
  compression, effect of, on very rapid heart, (4) 1239—ab
  conditions, acute, in very young infants, (36) 1085
  curetting, malignant chorioepithelioma diagnosed early by, (73) 1415—ab
  disease, continuous stream of oxygen in, (82) 1829—ab
  disease, diagnosis of, (27) 242, (17) 914
  diseases, liver dullness in, (73) 86
  drain, new, *1499
  emergencies, (1) 2098
  hysterectomy 63 hours after labor for necrosed and suppurating subperitoneal fibroid, (14) 324
  incision, extramedian, (143) 1420
  infection, acute, in typhoid bacillus carrier, (16) 1907
  massage in whooping cough and tracheobronchial catarrh, (65) 1242—ab, (93) 1486
  muscles, fibrosis of, (21) 2099
  muscles, paralysis of, on both sides, as most prominent symptom of anterior poliomyelitis limited to lower dorsal region (39) 84
  onset, deceptive, of certain diseases of children, (51) 1175
  pain in women, proptosis of left broad ligament cause of chronic constipation with, (77) 1580—ab
  Section, Operation: See Laparotomy
  surgery in America, early history of, *600
  surgery, in rare form of intestinal obstruction, (30, 33) 1907—ab
  surgery, obstetrics and gynecology, (6) 491
  surgery, practical points in (84) 819
  surgery, prevention of adhesions in, (61) 494, (83) 911—ab
Abdominal surgery, oil in prevention of adhesions in, (83) 911—ab
  surgery, factors of safety in (26) 1006
  surgical shock, new treatment for, (72) 742—ab
  sympathetic ganglia, shock of, produced by electric stimulation, (50) 740—ab
  viscera in umbilical hernia, (66) 909—ab
  viscera, reflex pain in diseases of, (2) 1239—ab
  viscera, sensibility of, (100) 826
  wall, excision of fat of, (99) 1409—ab
  wall, hernia in, aside from median line, (80) 1415
  wall, hematoma of, simulating desmoid tumor, (110) 495
  wall hernias, plastic periosteum operation for, (114) 329
  wall, plastic surgery of, (63) 740 (132) 1017, (65) 1343
  wall, thickness of fat in, as index of condition of nourishment in adults, (120) 1831—ab
  wall, transplantation of muscles for defects in, (65) 1343
  watersheds and their influence on localization of intraperitoneal infections, (3) 1410
Abortion, (79) 1168, (29) 1235, (39) 1647
  artificially induced, necessity for legal regulations in, (133) 1659
  cervico-vaginal fistula from, (182) 170
  contagious, in cattle, Bacillus abortus, cause of, (90) 2004
  criminal, legal status of, (56) 1236
  early, histologic changes with, especially in blood-vessels of decidua, (29) 1091
  habitual, treatment of, (66) 2008—ab
  incomplete, surgical treatment of, (48) 740
  inevitable and incomplete, treatment, (55) 1236
  intraperitoneal, in lower abdomen, proper treatment of, *2105
  miliary tuberculosis following, (110) 1095
  of ovum, menstruation sign of (37) 415
  septic, treatment of, (54) 1236
  therapeutic, indications for, consideration of rights of unborn child, (140) 1339
  treatment of, (62) 741—ab
Abscess, appendicitic, prognosis of, (33) 1341
  cavities and tuberculous sinuses, bismuth-vaselin-paste in, (47) 493
  cerebellar, and acute suppurative labyrinthitis, (8) 1906
  cerebellar, and purulent leptomeningitis, sinus thrombosis due to, (5) 1334
  fixation, in acute bronchopulmonary disease, (46) 915—ab
  in anal and rectal region, (22) 1907
  in nasal septum, traumatic origin of, (81) 825
  liver, (103) 411
  liver, cholangitic, (107) 1417
  of breast, suction hyperemia of, (24) 1654
  of spinal cord, (143) 420
  of spleen, (125) 1650
  of spleen, primary, (132) 1097—ab
Abscess of puerperal uterus, intramural, (52) 1236—ab
  old, in lung, cure of, by surgical pneumothorax, (88) 750—ab
  perinephritic (107) 1338—ab
  periurethral, *375
  prostatic, acute, (17) 1482
  pulmonary, following septic deglutition pneumonia, (49) 1823
  retropharyngeal, (101) 240, (93) 653
  subphrenic, (16) 914, (31) 2096—ab
  tuberculous, of chest wall originating in costosternal articulations, (42) 572—ab
Abscesses, corpus luteum, (48) 823
  liver, multiple, cholangitic, operative cure of, (70) 166
  tuberculous, of bony origin, treatment of, (4) 1172—ab
Absorption, action of phenol on, (145) 655—ab
  and digestion of food, laws for regulation of, (151) 1098—ab
  and elimination in regard to administration of drugs, (12) 565—ab
  from peritoneal cavity, influence of adrenalin on, (41) 1901—ab
  of protective glasses, spectrographic studies of limits of, (103) 654
Abstinence, total, fundamental errors of zealots of, (98) 1486
Acapnia and shock, failure of respiration after intense pain, (150) 744—ab
  and shock, fatal apnea after excessive respiration, (83) 494—ab
Acaro-dermatitis, urticarioides, (89) 1086—ab
Accident, industrial, hernia industrial disease not, (164) 1834
  surgical, necessitating intestinal resection, (5) 1005—ab
Accidents, electric, first-aid in, (122) 1017—ab

Accommodation, eyestrain due to, (43) 1006
Accouchement: See Delivery
Acetabulum, malformation of, (66) 824
Acetone alcohol disinfection, (130) 420—ab, (160) 421
  bodies in diabetes, importance of excretion of, and value of oatmeal courses, (88) 575
  bodies, relations of fat acids in organism with, (94) 1658
Acetonuria, clinical aspects of, (34) 657
  in infectious diseases, (15) 2006
  [illegible] and hyperesthesia [illegible] 1829
  [illegible] 2098
Achylia-gastrica, (93) 162, (138) 1018—ab
  intermittent, local asphyxia of extremities a complication of, (69) 819—ab
Acid: See also Acids
Acid, acetic, and mercuric chlorid test for bile pigments in stools, (55) 85
  acetic, test, for differentiating exudates and transudates, (79) 575
  benzoic, and sodium benzoate, effects of, *1774
  beta-oxybutyric, new mode of formation of, in animal organism, *1441
  boric, new aspect of effects of, as food preservative, (21) 1654—ab
Acid, camphor-carbolic, as direct antiseptic application to ulcerated surface, (36) 1412
  camphoric, efficacy of, in sweats in tuberculosis, (146) 1420—ab
  Carbolic: See Phenol
  carbonic, nascent, and oxygen baths, action of, in nervous conditions, (100) 1095
  chromic, experiments to determine toxicity of, in dilute aqueous solutions when injected intramuscularly; antidotal value for rattlesnake venom, (176) 1826
  hydrochloric, action of, on albuminoids, (68) 1093
  hydrochloric, in chronic diarrhea, (19) 565—ab
  hydrochloric, secretion, influence of hydrogen peroxid on, (67) 1007-ab
  Intoxication: See also Acidosis
  intoxications and their therapeutic indication, (142) 1825
  lactic, bacilli, new method of applying, in suppurating wounds, (20) 78
  lactic, in autolyzed dog's liver, (151) 323
  lactic, in metabolism, (39) 1654
  lactic, vaginal douches, unfavorable influence of, in obstetric cases, (91) 1586
  nitrous, nitric oxid and nitrites as cholera toxins, (85) 328
  nucleinic, cleavage products of, in autolysate of pneumonic lung, (86) 1345
  oleic, probably not responsible for eclampsia, (117) 662—ab
  osmic, in neuralgia, (86) 1007
  phosphoric magnesium and lime, metabolism of, in healthy and gouty, (172) 1834
  uroxanic, and iminoallentoin, physiologic behavior of, (184) 1652
Acidosis, (26) 651
  and anesthesia, (33) 914
  clinical estimation of, (16) 745
  coma from, due to suppurative inflammation of liver, (54) 916—ab
  diabetic, clinical determination of, (69) 825
  in diabetes, determination of intensity of, as guide to treatment, (75), 1243—ab
  in infants, determination of, (83) 749, (171) 1093
Acids, analyzing action of, on alcoholic fermentation, (54) 1908
  and salts, relative toxicity of, toward paramecium, (126) 240
  fat, fate of, in organism and relations with acetone bodies, (94) 1658
  fat, in intestines of infant, formation of, (97) 66
  glycuronic, paired, relation of glucosids to, (62) 573
  mono-amino, yielded by proteins when hydrolyzed with acids, modifications of methods for determining quantity of, (162) 1826
  organic, abstraction of calcium salts of lipoids in blood for neutralization of, (10) 1724
Acne and acneiform lesions, phototherapy and radiotherapy of, (53) 659
  bacillus, (11) 78—ab, (6) 2098
  bacillus, are seborrheic conditions of scalp due to? (44) 1907

- Acne, common, cause, symptoms and treatment, (23) 746—ab

  ether, death from, (80) 1086
  ether, explosion of ether fumes during x-ray examination in course of, (110) 827
  ether, general, intravenous, (87) 2009—ab
  ether, new method of giving, (35) 1827—ab, (44) 1828—ab
  ether, primary, long operations under, (128) 1017—ab
  ether, vs. nitrous oxid, (110) 569-ab
  fecal vomiting during, method of obviating its danger, (11) 1728—ab
  for intracranial surgery, (140) 912
  for prostatectomy, (7) 1005
  general, ethyl-chlorid-oxygen, (74) 328
  general, pupils in, (64) 567
  general, scopolamin and morphin as preliminary to, *1051
  general, surgical, (44) 1085
  general, technic for, (158) 1833
  general, to what extent can local anesthesia supplant? (72) 1177
  general, transient positive response to Wassermann reaction after, (100) 1417—ab
  general, with part of circulation shut off, (114) 828—ab, (76) 1917 ab—, (165) 1489—ab
  general, with part of circulation shut off, dangers of, (76) 917—ab
  hedonal, general intravenous, (104) 1178, (88) 2009
  hysterical, (50) 1647
  inhalation, general, scopolamin with, (60) 1242
  in obstetrics, (97) 911, (149) 1489
  intravenous, general, (140) 169—ab, (166) 422—ab, (93) 750—ab, (22) 822—ab, (130) 1017—ab, (113) 1095, (104) 1178, (88) 1244, (87, 88) 2009—ab
  intravenous, general, by cocain, (22) 822—ab
  intravenous, general, by hedonal, (104) 1178
  intravenous, general, dangers of, (99) 1178
  intravenous, local, (57) 567
  local, and major operations, (35) 1728—ab
  local, herniotomy under, (68) 1648
  local, in anorectal surgery, indications and limitations of, (25) 566—ab
  local, in dentistry, limitations of, (117) 89
  local, in ear surgery, (11) 1235
  local, in general surgery, (128) 163, (11) 651
  local, mastoid operation, simple and radical, under, (149) 1171
  local, quinin and urea hydrochlorate in (79) 1726
  local, quinin and urea hydrochlorid in, *1375, *1940
  local, supplemented by epinephrin anemia in operations on head and throat, (108) 1830
  local, unusual surgical case under, (41) 1823—ab
  nitrous-oxid-oxygen, by method of rebreathing, *775
  nitrous oxid, in surgery, *1589
  nitrous-oxid-oxygen, in thoracic surgery, (86) 568—ab
  prolonged, dangers of, (35) 1085
  quinin and urea hydrochlorid for local, *1375
  rectal, (14) 1646
  rectal, apparatus for, (174) 1089—ab
Anesthesia, regional, (104) 240
  sacral, in obstetric cases by epidural injections, (149) 1489
  scopolamin-morphin, *446, *516, (9) 1411—ab
  scopolamin-morphin-chloroform, mishap after, (102) 1417—ab
  scopolamin-morphin, influence of, on metabolism, (54) 1725—ab
  scopolamin-morphin, two fatalities under, (52) 748—ab
  spinal, (27) 164, (91) 244—ab, (173) 1089, (15) 1166, (31) 1406, (10) 1411, (78) 2097
  spinal, and pituitary extract for forceps delivery during acute pneumonia, (5) 2140
  spinal, death under, by Jonnesco's method in acute intestinal obstruction, (10) 1411
  spinal, histologic changes on ganglion cells of spinal cord in, (98) 1830—ab
  spinal, history, anatomy and technic of, (82) 660
  spinal, in infant, enterectomy for intussusception under, (15) 822
  spinal, stovain, *281, (89) 1580
  spinal, stovain, modified technic for, (120) 1017, (73) 1177
  stimulation during, (137) 1906
  surgeon's responsibility during, (8) 2095
Anesthetic attachment for bronchoscope, (157) 1171
  elimination of, by promotion of diuresis, (43) 823—ab
  emergency apparatus for administration of, *1208
  general, chloroform vs. ether as, (42) 1828
  index, (94) 81
  local, ethyl chlorid as, (94) 1726
  local, quinin and urea hydrochlorate as, (79) 1726
  practice, 10 years of, in incorporated dental hospital of Ireland, (18) 2098
Anesthetics, administration of, (136) 1088
  advantages of combination of, (101) 1346
  and anesthesia, (114) 1904
  cutaneous action of, (11) 1173—ab

  in amebic dysentery, *503, (83) 819
  in epilepsy, (71) 494—ab
  new method of, *868
Appendix, (64) 237
  abscess, prognosis of, (33) 1341
  analysis of 1,411 operations on, (47) 1236
  and cecum, inversion of, (15) 241
  and right ureter, anatomic, pathologic and clinical studies of lesions involving, *1491
  and stomach, x-ray examination of, (56) 165
  a pelvic organ, appendicitis when, (18) 242
  cancer of, radium emanations in, (9) 913—ab
  carcinoma of, (63) 1585—ab
  carcinoma, primary, in, (115) 168, (85) 1094
  cases, series of, (78) 819
  chronic diseases of, (135) 1650
  connection of gastric hypersecretion with latent diseases of, (9) 1240—ab
  cysts and diverticula, (63) 166
  dyspepsia, (8) 745—ab
  end-results of non-removal of, in 23 abscess cases, (136) 1906
  Fallopian tubes and right ovary, cancer of, (31) 1012
  gastralgia due to, (10) 1240—ab
  healthy looking, which may be diseased, (21) 498—ab
  incarceration of, in hernia, and appendicitis, (74) 825
  in intestinal catarrh, especially in children, (160) 1913
  localization, pathognomonic signs of, (30) 237—ab
  matastasis in, with mammary carcinoma, (88) 1585
  palpation of, (141) 1488
  pathology of, (144) 1650
  peritoneal pseudomyxoma originating from, (14) 1340
  polycythemia disappearing after removal of, *1207
  pseudoinvagination of, (62) 166
  rupture of traumatic, (148) 1489—ab
  stump, management of, *2
  tuberculosis of, (69) 1485—ab, (72) 1909—ab
  vascularization of segments of, and appendicitis, (94) 826
Appendotome, (109) 162—ab
Appetizers and relish, (113) 1658
Appliance: See Apparatus, and Instrument
Arbacia, action of isotonic solutions of neutral salts on unfertilized eggs of, (135) 1481—ab
Arc and incandescent light in medicine, (26) 78—ab
Arginin, determination of, in autolysate of pneumonic lungs, (85) 1015
Aristol, dermatitis from, *2042

Arm, action of short rotators on normal abduction of, and on subacromial bursitis and allied conditions, (52) 79
  and shoulder, fracture of, apparatus for automatic extension of, (142) 169—ab
  cellulitis of, complicated with pneumonia, vaccine therapy in, (15) 1907
  deep painful angioma on, (52) 416
  device for support of, (114) 1408
  neuralgiform pain in, due to shoulder arthritis, (120) 419—ab, (120) 1096
  proximal paralysis of, of cortical and subcortical origin, (143) 663
  retroversion of, with operation for correction, (105) 1726
  right, ectro-hemimelia of, (64) 1236
  subtotal and total excision of scapula, with and without retention of, (91) 1094
  tumor in, studied from neurologic and surgical standpoints, (28) 2141—ab
Arms, angiectasia of, (142) 829
  crushed between rollers, treatment of, (79) 1094
  malformation identical in, (103) 1008—ab
  of precision, (153) 1410—ab
Army, eradication of specific urethritis from, by K package, reenforced by military law and discipline, (96) 240—ab
  factors essential to efficiency of medical officers in, (52) 2096
  German, diagnostic tuberculin tests in, (117) 1346
  German, training for disinfection service in, (109) 1346
  importance of diseases transmitted by mosquitoes to, methods for prevention of, (94) 1168
  Medical Corps as a career, *1120
  medical service, (107) 1727
  medical work in Philippines, (36) 566
  Navy and Public Health and Marine-Hospital Service, possible relations between, under limitations of existing law, (132) 913
  psychiatry in, (62) 1484
  venereal disease in, and necessity of proper action by state and municipal authorities for its effectual control, (98) 240
  what should be relation of American National Red Cross to medical departments of? (49) 1578
Arrhythmia, extrasystolic, simulating heart block, (143) 1170
  paroxysmal, tuberculous, (49) 1343—ab
Arrow poisons in Congo, (139) 1097
Arsacetin in pseudoleucemic glandular disease, (114) 1096
  optic atrophy under, (78) 1014
  toxic by-effects of, irritating action on kidneys, (94) 1177
  treatment, findings in central nervous system of mice under; artificial dancing mice, (97) 329
Arsenic and mercury, injection of salts of, during reaction period following tuberculin injections for tuberculosis, (6) 2139—ab
  in organic nervous diseases, (76) 1585—ab
  iodids and mercury, (30) 1578
Arseno-phenyl-glycin, action of, on Trypanosoma brucei, (114) 496
Arsobenzol, single large dose of, in relapsing fever, (77) 1730
Artaeus the Cappadocian, (54) 410
Arterial and venous systems, importanec of, in diseases of other organs, (49) 410—ab
  hypertension, (28) 1822
  pressure, apparatus for graphic registration of, in health and disease, (48) 1655
  occlusion, permanent, after deligation, demonstration of process of, by experimental studies on animals and operations on human beings, *1301
  system, hypertension and sclerosis of, rational treatment of, (113) 820, (43) 1647
  tension, phototherapy in, (118) 1650
Arteries, changes in walls of, during or preceding menopause, due to disturbances in internal secretions, (94) 1486
  coronary, and papillary muscles in heart, (115) 1016
  diseases of, experimental, in rabbit, various forms of, (53) 651—ab
  large, growth and aging of, and their relation to pathology of vascular system, (76) 2101
  modification in structure of, in chronic nephritis, (158) 1489
  pulmonary, primary thrombosis of, and sudden death in puerperium, (44) 84
  reactions on part of elastic tissue of, (32) 2006
  renal, abnormal, pathogenic rôle of, (54) 1828
  retinal, intermittent closing of, *2118
  subclavian and brachial, gunshot wound of, (112) 1016
Arteriosclerosis, (20) 1235
  a factor in insanity, (108) 2005
  and allied conditions, (16) 83
  and higher blood-pressure, experimental chronic nephritis with, (84) 1480—ab
  and palpability of artery walls, (86) 418
  and resulting changes in blood-vessel nerves, (144) 420
  cerebral, symptomatology of, (107) 920—ab
  condition preceding, (43) 1342
  etiology and treatment of, (79) 749—ab
  eye symptoms of, (30) 1006
  nervous and mental manifestations of, (112) 1338
  of bladder, (33) 1725
  splanchnic, (37) 556
  treatment of, *104, (123) 1169, (73) 1726
  treatment of, or general arterial fibrosis with D'Arsonval current, (67) 741
  visceral, clinical aspects of, (115) 1727
Arteriospasm, paroxysmal, with hypertension in gastric crises of tabes dorsalis, (26) 1822—ab
Arteritis and arterial embolism with uterine fibroma, (79) 1829
  nodosa, case of, (116) 1016
Artery anesthesia, 349—ab
  blood pressure in and suprarenals in tuberculous patients, (28) 1241—ab
  carotid, common, aneurism of, treated by ligation of innominate, (118) 1911
  carotid, external, ligation of, *1301
  carotid, internal, aneurism of, treated by Matas' method, (50) 566—ab
  hepatic, ligation of, (78) 500—ab, (162) 1489
  iliac, ulceration of, in contact with drain, (42) 1092—ab
  innominate, ligation of, for arterio-venous aneurism of common carotid, (118) 1911
  mesenteric, superior, embolism of, *700
  or vein wall, advantages of, for plastic operation on dura, (102) 1909
  popliteal, aneurism in, endoaneurismorrhaphy for, *1443, *1942
  popliteal, aneurism of, modern treatment of, (49) 1092—ab
  pulmonary, embolism of, and venous thrombosis, (85) 87—ab
  pulmonary, sclerosis and atheroma of, (59) 1908
  renal, pathologic changes in kidney as result of occlusion by ligature of one branch of, (121) 911
  walls, arteriosclerosis and palpability of, (86) 418
  walls, finger-nail palpation of, (87) 1345—ab
Arthritic diathesis, special features of, (54) 1484
Arthritis, acute, of doubtful origin, (3) 1727
  chronic, surgical treatment of, *771
  deformans, (20) 1406, (14) 1583—ab
  deformans after typhoid, (67) 917
  deformans of hip, new operation for, (104) 1408
  deformans, pain of, (56) 2100—ab
  deforming, isolated, of sigmoid cavities of elbow, numerous free bodies in, (82) 328
  dry, injection of petrolatum in, (47) 237
  due to sporothrix, (42) 1413—ab
  gonorrheal, (40) 1647
  gonorrheal, cryptogenous, acute, (147) 331—ab
  gonorrheal, vaccine therapy of, (23) 1827
  non-tuberculous, chronic, (68) 909
  of elbow, (82) 328
  purulent, drainage of knee back of condyles with, (60) 1584
  shoulder, responsible for neuralgiform pain in arm, (120) 419—ab, (120) 1096
  tuberculous, (37) 2096
Arthopathies, syphilitic, (137) 1410
Arylarsonate and mercurial treatment of syphilis, (7) 413
Arylarsonates in pulmonary tuberculosis, (19) 656
Ascarides lumbricoides, intestinal obstruction from, *2041
Ascites and enlarged spleen, cirrhosis-of-liver with, pathology of, (84) 1657
  autoserotherapy of, (51) 915—ab
  enormous, (9) 1084
  in new-born infant, (92) 750
  hepatic, surgical treatment of, (32) 320
  splenomegaly and cirrhosis of liver, (143) 1018
  with enlargement of liver, in Nyasaland, (24) 1483
Asepsis, evolution of, (89) 161
  importance of suture technic for, (80) 328, (148) 1098
  in home deliveries, dire results of trusting alone to, (170) 1834
Asphyxia, anesthesia, immediate massage of heart in, (115) 246—ab
  local, of extremities, a complication of intermittent achyliagastrica, (69) 819—ab
Aspidosperma, experiments with alkaloids of, (78) 1648
Aspiration and insufflation in middle-ear diseases, (70) 494
  apparatus for, (48) 158
Aspirator, blood, *1690
Asterias, action of isotonic solutions of neutral salts on unfertilized eggs of, (135) 1481—ab
Asthenia, general, importance of, (70) 1013
Asthenopia, amber-tinted lenses for relief of, (119) 1238—ab
Asthma, acute, adrenalin in, (8) 1011—ab
  apparatus for treatment of, (112) 1658—ab
  bronchial, advantages of electric incandescent baths in, (88) 1657
  bronchial, and chronic bronchitis, x-ray in, (73) 2008
  bronchial, technic and results of respiratory exercises in, (115) 1417
  spasmodic, hypodermic injections of adrenalin in, (14) 2098—ab
  spasmodic, treatment of, (19) 572—ab
[illegible] with meridians [illegible]t crossing at [illegible]09 [illegible] 2002
Asymmetry and symmetry, effect of, in lateral curvature of spine, (128) 412
Asystole of left side of heart, characteristics of venous jugular pulse in, (40) 1729
Ataxia, cerebellar, (7) 2002
  Friedreich's (7) 570—ab
Atheroma and sclerosis of pulmonary artery, mechanical factors in, (59) 1908
Athlete, life of, and degenerative changes in cardiovascular system, (10) 1334
Athletes, urine sediment in, (77) 1344
Atlas and exis, traumatic lesions of, (50) 1085, (114) 1238
Atlo-axoid fracture dislocation, (51) 1085
Atmosphere, investigation of extent of bacterial pollution of, by mouth spray, (68) 568—ab
Atmospheric and similar conditions, predisposition to disease with, (110) 1911—ab
Atomizer, easily sterilizable, *374
Atony and tonics, (24) 651
Atoxyl iodid treatment, intravenous, of exophthalmic goiter, (104) 919
  poisoning, (120) 168
Atresia and stenosis of gastrointestinal tract with imperforate anus, case of, *704
  node, and blood supply of sinus node, (138) 169
Atrophy, bone, x-ray study of, (101) 1337
  muscular, (97) 1408
  muscular, and tabes dorsalis, (10) 1901
  muscular, syphilitic, chronic, and tabes dorsalis, (46) 2007
  of aorta, chronic, syphilitic, (56) 1343
  of integument a sign of diagnostic importance in early pulmonary tuberculosis, *2123
  optic, under arsacetin, (78) 1014
  segmentary, of colon, (73) 243—ab
  yellow, acute and combined intoxication and bacterial infection, (45) 1901
  yellow, acute, of liver, alcohol-soluble hemolysins in, (52) 1729
Atropin, behavior of involuntary muscular contractions with, (26) 657
  in ileus, (71) 575—ab
Auricle and ventricle, mechanism of regulation in complete dissociation between, (95) 418
Auricles, electrocardiographic curves yielded by ectopic beats arising in walls of, (16) 1411
  bundle, a conspicuous lesion in path of, Adams-Stokes disease with complete heart block, (31) 492
  bundle, and Adams-Stokes syndrome, (75) 1344
Auscultation in testing heart functioning before and after light exercise, (169) 1914—ab
Auscultatory differences between sides of normal chest, (46) 79—ab
  friction, (8) 2005
  phenomenon met in infants and children, 1685
  sign in morbid conditions of lungs or pleura, physical explanation of, (30) 325
Autodigestion of intestine implanted in stomach, (101) 826—ab
Autodrainage, autoserotherapy of tuberculous peritonitis by, (74) 1730—ab
Autoinfection and rubber gloves, (86) 918—ab
Autoinoculation of chancres, spontaneous and experimental, (57) 1343
  of spleen, resistance produced in mice against transplanted cancer by, (148) 413—ab
Autointoxication due to restricted diet, (70) 1903
Autolysate of pneumonic lung, cleavage products of nucleinic acid in, (86) 1345
  of pneumonic lungs, determination of histidin, arginin and lysin in, (85) 1345
Autolysins in blood in advanced pulmonary tuberculosis, (81) 575
Autolysis, aseptic, of liver, histophysiologic research on, (44) 658
  of pneumococci and effect of injection of autolyzed pneumococci, *1943
Automatism, phases of, in epilepsy, (72) 1408
Automobile and physician, 1245 to 1276
  as curative factor in catarrhal and bronchial diseases, (80) 1168
Autopsy after death from embolism of abdominal aorta with mitral stenosis and thrombosis of pulmonary veins, (5) 1652
  findings in familial hypertrophic neuritis of Pierre Marie type, (70) 1485
  of acute hemorrhagic pancreatitis, (11) 1334
Autoserotherapy, in pleurisy with effusion, (142) 1018
  of ascites, (51) 915—ab
  of tuberculous peritonitis by autodrainage, (74) 1730—ab
Axilla, involvement of, after primary facial infection with gonorrhea, *1440
Axis and atlas, traumatic lesions of, (50) 1085, (114) 1238
  vertebra, fracture of, reduction, recovery, (21) 83—ab
Azotemia, (157) 1489
Azure-eosin staining of sections, (83) 1485

B

Babies, advantages of being nursed by tuberculous mothers, free from open lesions, (95) 1486
  class, constipation as treated in, (55) 1407
Baby-tent idea, (29) 1725—ab
Bacilli: See also Bacillus
Bacilli, acid-alcohol-resisting, in blood, (155) 913
  anthrax, technic for showing capsule of, (102) 1732
  diphtheria, simplified Neisser stain for, (99) 1417
  lactic acid, in gonorrheal and mixed infections of female genitalia, (15) 656—ab
  lactic acid, new method of applying, in suppurating wounds, (20) 78—ab
  lactic acid, preparations of, and production of soured milk, (11) 241
  lactic acid, therapeutic value of, (12) 2095
  parasites resembling, found in red corpuscles of Brazilian frog, (44) 1483
  paratyphoid, and meat poisoning, (78) 659, (70) 1177
  tetanus, in inguinal glands, rusty nail tetanus with, (10) 236
  tubercle, (153) 413—ab
  tubercle, acid-fast and acid-semi-fast, study of, *1591
  tubercle, accidental contamination with, of meat from non-tuberculous animals, (50) 1655

Bacilli, tubercle, biochemistry of, (80) 1585
  tubercle, bovine, infection of man with, (71) 917
  tubercle, bovine, virulent, living, immunity production in rabbits by inoculation of increasing numbers of, (120) 911
  tubercle, cultures of, calcium chlorid method for enriching, (131) 1832
  tubercle, destructive action of ovarian substance on, (148) 421
  tubercle, determination of, in placentas of tuberculous mothers, (80) 2009
  tubercle, determination of, in sputum, (81) 918
  tubercle, determination of, in larynx mucus, (147) 830—ab
  tubercle, differences in precipitins produced by, (134) 1825
  tubercle, found in clinical laboratory work, are acid-fast bacteria the same as, (4) 1405—ab
  tubercle, from swallowed sputum, in stools, (91) 750
  tubercle, granular non-acid-fast form of, (149) 1098
  tubercle, human, transformation of, into bovine type, (87) 750
  tubercle, in blood, (19) 78, (101) 322—ab, (35) 492, *593, (55) 818
  tubercle, in blood, detection of, by Rosenberger's method, (36) 739—ab
  tubercle, in gastrointestinal tract, and antiperistalsis, (124) 912—ab
  tubercle, in intermuscular lymph glands in general tuberculosis in cattle, (145) 421
  tubercle, in sputum and urine, improved technic for detection of, (131) 663
  tubercle, in sputum antiformin for detection of, (145) 1488, (136) 1825
  tubercle, in sputum, comparison of technics for determination of, (22) 2141
  tubercle, in sputum, determination of, by Ellermann-Erlandsen technic, (83) 244
  tubercle, in sputum, glandular form of, (144) 330
  tubercle, in sputum in pulmonary disease, (72) 917
  tubercle, latent occurrence of granular form of, (109) 88
  tubercle, retention of vitality of, in flowing waters, (23) 2141
  tubercle, stained with methyl-violet-fuchsin, morphologic and biologic research on, (64) 1414
  tubercle, staining of, (42) 1241, (64) 1656, (55) 2100
  tubercle, staining of fuchsinophile and gramophile forms of, (12) 1646—ab
  tubercle, transformation of human and bovine types of, and question of cattle immunization, (135) 1825
  typhoid, formalized cultures of, for agglutination test, (13) 491
  typhoid, isolation of, from blood of typhoid patients, (79) 1648—ab
  typhoid, non-agglutination of, by tuberculous' serum, (108) 577—ab
  typhoid, rapid cultivation of, from blood clot after digestion in trypsin-containing beef gall, (100) 418
Bacillus abortus, cause of contagious abortion in cattle, (90) 2004
  acne, are seborrheic conditions of scalp due to? (44) 1907
  aerogenes capsulatus, emphysematous gangrene due to, treatment of, (13) 2095—ab
  aerogenes capsulatus in infections in obstetric cases, (134) 330
  aerogenes capsulatus infections, *1671
  aerogenes capsulatus infections, treatment of, by proximal injections of hydrogen peroxid, (12) 78—ab
  bifidus communis, pleomorphism and pleobiosis of, (86) 1237
  Boas-Oppler, significance of, in stools in carcinoma of stomach, (87) 1007
  carrier, typhoid, acute abdominal infection in, (16) 1907
  carriers and prophylaxis of transmissible diseases, (171) 332—ab
  carriers, diphtheria, chronic, cure of, (172) 422—ab
  carriers, diphtheria, in public schools. *951
  carriers, diphtheria, removal of adenoids and enlarged tonsils effectual in curing, (173) 332
  carriers, opsonic index of, *704
  carriers, treatment of, (76) 659, (38) 914
  carriers, typhoid, (129) 743, (4) 1234, (13) 1411—ab, (38) 2142—ab
Bacillus carriers, typhoid, and prophylaxis of typhoid in French army, (41) 1012—ab
  carriers, typhoid, laboratory diagnosis of, (31) 237
  carriers, typhoid, value of opsonin determinations in discovery of, (86) 2005—ab
  colon, action of, on uterine and vaginal mucosa, (59) 326
  colon, acute pyelonephritis due to, (37) 1907—ab
  colon and B. typhosus group of bacteria, seroreaction in healthy to, (104) 1732
  colon and streptococcus vaccine in urinary diseases, (79) 1007—ab
  colon, cause of formation of uric acid, (142) 663—ab
  colon group, emphysematous gangrene due to member of, (46) 908
  colon, infection and colon bacillus pneumonia, typhoid with, (98) 1417
  colon, infection of female urinary passages in pregnancy and puerperium, (56) 1414
  colon, individual strains of in children, (100) 750
  colon, infection, acute, subacute, and chronic, of kidneys, (1) 2002
  colon, infection of urinary tract, (105) 1337, (21) 1583, (25) 1822, (106) 1904, (1) 2002
  colon, infection of urinary tract, vaccine therapy in, (37) 1012
  colon, pneumonia, and colon bacillus infection, typhoid with, (98) 1417
  diphtheria and pseudodiphtheria, (82) 2004—ab
  diphtheria, latent infections by, and administrative measures for dealing with contacts, (38) 914
  diphtheria, latent infections of, (34) 823
  fæcalis alcaligenes pathogenic for man, (95) 919—ab
  fusiformis, in membranous affections *of throat*, (122) 654
  influenza, action of liquid kolynos on, (13) 2098
  influenza and symbiosis, (6) 1906
  influenza, cause of epidemic of bronchopneumonia, (4) 82—ab
  lactic acid, experiences with, (29) 164
  lepra, *cultivation of*, (117) 1905—ab
  lepra, in circulating blood, (70) 1726—ab
  mallei, virulence of old cultures and subcultures of, *699
  new, in trachoma, cultivation of, *965
  of acne, (11) 78—ab
  of Malta fever, pyogenic properties of (144) 248
  perfringens and bacillus of acute articular rheumatism, crossed cultivation of, (50) 658
  proteus, found in case of accidental hemorrhage and chronic uremia, (37) 325
  proteus in gastrointestinal infection, (67) 243
  pseudodiphtheria, in suppuration in man, (59) 1012
  pyocyaneus, animal charcoal in lesions caused by, (109) 1016
  typhoid group of bacteria and B. colon, seroreaction in healthy to, (104) 1732
  typhoid, in development of suppuration, (93) 918
  typhoid, modified Hessé's medium for detection of, in excreta and fluid foods, (146) 1481
Back, causes and characteristics *of* pain in, (78) 1657
  contusions of, and their complications, (142) 1339—ab
Backache, chronic, experimental study of, *1033
Bacteria, aciduric—acidophilic, (126) 912
  acid-fast, are they other than tubercle bacillus found in clinical laboratory work? (4) 1405—ab
  acid-fast, in distilled water, (11) 408—ab
  acid-fast, true carbol-fuchsin iodin stain for structure of, (87) 1909
  action of sodium benzoate on multiplication and gas production of, (159) 324—ab
  connection between plasmolysis, *digestibility*, solubility and staining properties *of*, (95) 1658
  destructive influence of *osmotic* currents on, (139) 169
  distribution of, in bottled milk and controlling *factors*, (85) 2004—ab
  fate of, in entering lymph glands by *inhalation* or through cutaneous lesions, (73) 500
Bacteria, improved technic for differentiation of, (121) 247
  in circulating blood; technic for demonstration by staining methods, (30) 78
  influence of balsam of Peru on, (121) 1911—ab

  internal, ligation of, (57) 740
  region, primary syncytium-endothelioma of lymph gland in, (136) 420
Carpometacarpal articulation, dislocation of, (166) 1913
Carrot soup in infants' digestive disturbances, indifferent experiences with, (84) 750
Cartilage, action of lime ions on water-absorbing power of, (102) 245
  production of, in healing fractures, (148) 1420
Cartilage, transplantation of, in deformities of nose, (19) 1166
  triangular, of nose, expeditious method for submucous resection of, (91) 653—ab
Cartilages, semilunar, displacements of, (8) 570
Case, famous, recalled, (41) 818, (38) 1336
Case records and careful history taking, importance of, (102) 411
Casein content of human milk, (89) 1415
  curds in infants' stools, (99) 495, (85) 1086, (159) 1826
  effects of carbohydrates on artificial digestion of, (146) 569—ab
Castor pomace, poisoning from inhalation of, (88) 1408
Castration, effect of, on metabolism, (117) 1169—ab
Casts, origin and significance of, (146) 744
  phosphatic, of unknown origin, complicating gonorrhea, (49) 2096
  plaster, vinegar for softening, to cut in removal of, (83) 918
  tube, improved India ink technic for demonstration of, (94) 501
Catalase of echinoderm eggs before and after fertilization, (128) 240
Catalytic-activity of blood, relation of, to number of red blood cells in health, and to number of white blood cells and body temperature in peritonitis, (145) 413—ab
  of developing hen eggs, (146) 413
Cataract, (95) 162, (37) 1823
  absorption, (33) 2002
  arrangement of capsule of lens after simple extraction of, (14) 1166
  congenital, interesting case of, (7) 821—ab
  congenital, is it caused by dystocia, (15) 817
  congenital, of unusual type, (121) 1480, (165) 1651
  congenital, successful operation at age of 23, (6) 1166
  diabetic, prognosis of, (53) 915—ab
  due to electric shock, (162) 1651
  extraction (64) 410
  extraction in capsule, (108) 81, (92) 495, (100) 654, (27) 822, (124 to 131) 1088, (114) 1727, (28) 1827, (122 to 124) 1905
  extraction in capsule, attitude of profession toward, (131) 1088
  extraction in capsule by Major Smith's method, (92) 495, (100) 654, (27) 822, (114) 1727
  extraction in capsule, Malromez's operation for, (125) 1088
  extraction in capsule, toilette and after-treatment of, (130) 1088
  extractions, results obtained and features of interest in, (55) 410
  extractions, prevention of prolapse of iris after, (66) 1093
  juvenile, several cases of, in one family, (48) 2003
  operation on insane, (13) 1334
  senile, pathogenesis of, (51) 1484
  senile, successful removal of, from eyes of lepers, (65) 1824
  syphilitic presenile, (98) 1480
Catarrh, acute otitis media due to, treatment of, (131) 1488
  acute inflammatory affections of throat and posterior nares due to, and malaria, (95) 2005
  and bronchial diseases, automobile as curative factor in, (80) 1168
  chronic, of large intestine, hot gelatin injections in, (87) 1731-ab
  gastric, acute, (148) 323
  nasal, septum as factor in, (146) 323
  non-suppurative or dry of middle ear, factors producing, (147) 82
  of upper air passages, (37) 1578
  of upper air passages, abdominal massage in, (65) 1242—ab, (93) 1486—ab
  treatment of, (160) 1088
Catgut, aseptic, (127) 90, (62) 1242
  iodin, dry, (15) 571—ab
  ligatures, improved preparation of, (108) 1825—ab
  or unabsorbable suture material? (96) 576—ab
  sterile, production of, (125) 1911
  uses of, in surgery, (2) 324—ab
Cathartics in incipient peritonitis, harm in, (9) 738
Catheter, false passages caused by, (48) 1828
  in urethra, remarkably large vesical calculus attached to, removed by suprapubic method, (7) 2095
  lubrication of, by boiling vaselin in water with, (167) 1490—ab
  ureteral, diagnostic value of distention of renal pelvis through, (38) 320, (54) 741—ab
  ureteral, use of, (6) 636, (4) 821
Catheterization, aseptic, (121) 1488
  electric, (95) 1417—ab
  ureteral, and cystoscopy in male, (84) 1618
  ureteral, regurgitation from bladder to kidney during, (27) 1406
Catheters, various, for Eustachian tube, (156) 1651
Catsup, pure food, new, (29) 1085-ab
Cattle and carabaos, difference in susceptibility to cattle plague among, (119) 1904
  and pigs, practical experience with intradermal tuberculin reaction in, (63) 1636
  contagious abortion in, due to bacillus abortus of Bang, (90) 2004
  immunizing against anticattle-plague serum, (35) 1336
  immunization and transformation of human and bovine types of bacillus, (135) 1825
  microbe of peripneumonia, (51) 1908
Cauda equina, removal of fibrosarcoma in, (92) 1094
  tuberculosis, mastitis due to, influences determining prevalence of, (10) 2006
Caustic, stenosis of esophagus and pylorus from action of, (55) 1828
Cauterization of nose, influencing of cardiac neuroses by, (71) 1177-ab
Cautery, actual, technic of application of, during irrigation urethroscopy, (127) 1017
  electrolysis and refrigeration, in nevi and other skin lesions, (3) 82—ab
Cavalry in field, medical service with, (101) 1168
Cavernous sinus thrombosis, (100) 820
Cavities, large, in long bones, methods of treatment, (149) 1660—ab
Cavity formation, central, in spinal cord due to trauma without fracture, or dislocation of vertebræ, (91) 568
  left after operation for osteomyelitis in clavicle or tibia, graft of muscle tissue for filling of, (53) 1484
  photo-projectoscope, *534
Cecostomy and appendicostomy, therapeutic adaptations of, *753
Cecum, adherent inguinal hernia of, (58) 658
  and appendix, inversion of, (15) 241
  and colon, resection of, (65) 1478
  cancer of, complicating myoma, (40) 242
  in subhepatic position, appendicitis with, (8) 2140—ab
  inflammation of, (77) 328—ab
  inflammatory tumors in, (113) 577
  movable, habitual torsion of, (107) 1095—ab
  tuberculosis of, symptomatology and differential diagnosis of, (19) 817
  tumors of, (34) 320
Celiac plexus, pain in, (96) 1732
Cell division, physiology of, (135) 1481—ab
  forms, peculiar, in dental granuloma, (154) 1913
  sphenoethmoidal, and sphenoidal sinus, examination of skulls with reference to, (40) 914
Celloidin technic for series of sections, (82) 1585, (139) 1660
Cells and fluids of body, activity of, in prevention and cure of disease, (9) 1727
  decidua, importance of, (95) 1830
  disintegrated, living and mechanical, contrast in reactions in implantation of cancer after inoculation of, (6) 1340
  eosinophile, artificial increase of, in dementia præcox, *254
  ganglion, does optic nerve atrophy in tabes develop from disease of, or from nerve fibers? (127) 1905
  ganglion, of spinal cord, histologic changes in, in spinal anesthesia, (98) 1830—ab
  mast, in human and animal blood, action of injections of serum on, (74) 1344

Commissions: See also Medical Fees
Commissions and fee to physicians, division of, (95) 321—ab
  payment of, by specialist to general practitioner, (96) 321—ab
Communication, privileged, (80) 1485
Communities, means for better protection of, from disease, and by which aged physicians can be assisted, (87) 321
Compensation, failing, importance of functioning of peripheral blood vessels with, (118) 1347—ab
  failing, in chronic valvular disease of heart, treatment of, (159) 1088
  lost, treatment of conditions secondary to, (37) 1235
Complement, behavior of, in seroreaction, (65) 917
  destructive effect of shaking on, (75) 166, (82) 500, (135) 1018
  deviation in hydatid disease, (30) 1412
  deviation in pseudoleucemia, (80) 2101—ab
  fixation and bacteriolysis, amboceptors in, (122) 912—ab
  fixation, diagnosis of tuberculosis by, (48) 572—ab, (36) 1012, (113) 1178
  fixation in differentiation of natural and artificial honey, (116) 1417
  fixation in gonorrhea, (78) 568—ab
Complement fixation in leprosy, (34) 1822—ab
  fixation in rabies, (43) 1901
  fixation in syphilis, (3) 656—ab, (78) 1726
  fixation reaction, and streptococcus of scarlet fever, (27) 1583
  fixation, with lecithin as antigen in pellagra, (137) 82—ab
  hemolytic, variation of, in experimental trypanosomiasis, (29) 1483
  hemolytic, proportion of, in infant's blood serum not index of child constitution, (123) 329
Complements in breast milk, (122) 329
Compressed-air illness, (37) 1725
  illness, etiologic factors in, (71) 1168—ab
  illness, prophylaxis and treatment, (94) 1909
Conception and myoma, (93) 329—ab
  influence of venereal diseases on, (112) 1087—ab
Concrements, importance of colloids for formation of, (57) 1730
Concussion, remote effects of, (69) 1408
Condyle, outer, of tibia, fracture of, (113) 329
Condyles, drainage of knee back of, with purulent arthritis, (60) 1584
Conjugate, diagonal, sources of error in digital measurment of, (71) 417—ab
  true, enlargement of, by inducing lordosis, (130) 829—ab
Conjunctiva, palpebral, hypertrophy of, (41) 409
  pneumococcus in secretion of, in acute lobar pneumonia, (114) 1179—ab
Conjunctival sac, enucleation necessitated by getting point of aniline pencil into, (178) 1652
  sac, injury to eye from anilin pencil in, (62) 909
  secretion, trachoma bodies in, (46) 1729—ab
Conjunctivitis, eczematous, blepharotomy for, (57) 2007
  gonorrheal, metastatic, (111) 1649
  Parinaud's, with unusual complications, (126) 743
  phlyctenular, recurring, operative treatment of, (98) 501
Connective-tissue, contractile elements in, (12) 738, (1) 1405, (9) 1646, (13) 1822
  subcutaneous, localizations of acute articular rheumatism in, (43) 415—ab
Constipation, albuminuria due to, (45) 2100
  as treated in babies' class, (55) 1407
  chronic, (14) 1084, (146) 1339
  chronic, agar-agar in, (29) 1583
  chronic, paraffin treatment of, (108) 245—ab
  chronic, with abdominal pain in women, proptosis of left broad ligament cause of, (77) 1580—ab
  habitual, x-ray photographs of child subject to, (17) 2006
  neglected, effects of, in school girls, (19) 1240
  spasm of colon and alleged spastic form of, (64) 417—ab
  treatment of, (4) 1900
Constitutional diseases due to degenerate tonsils, (148) 1825
Constriction bands, uterine, complicating labor, (17) 1406
Contacts, diphtheria, administrative measures required for dealing with, (38, 39) 914
Contagion, source of, in epidemic typhoid, (103) 2010
Contagious and infectious, definition of, (154) 1825
Contract Practice: See Practice
Contractions, muscular, involuntary, significance of, and behavior with atropin in pathology, and treatment of gonorrhea in male, (26) 657
Contracture and tension of muscles in children, (66) 86
  and spasticity, cause of, in cases showing no demonstrable lesion of pyramidal tracts, (84) 239
  of Volkmann and ischemic paralysis, (84) 1829—ab
Contusions and distortions of spine, consequences of, (52) 1012
Convulsions, psychogenetic, (49) 1647
  puerperal, why are there so many? (57) 493
  uremic, calcium in, (106) 1480
Cooks, muscular spasms due to heat in, on Pullman diners, *1517
Coolness and warmth, instrument for ready clinical investigation of sensibility to, (66) 1478—ab
Cord degeneration, combined, subacute, (137) 1170

- Cord, umbilical, shortening of, from coiling around fetal neck, (45) 2003
- Cordectomy for bilateral abductor paralysis, with demonstration of specimen, (100) 2005
- Corn and pellagra, *452
- Cornea, nodular opacity of, cured by excision, (75) 410
  - operative treatment of recurring eczematous lesions of, (92) 825
  - serpiginous ulcer of, course and treatment, (77) 2101
  - serpiginous ulcer of, etiology and pathogenesis of, (124) 1179
  - technic for plastic operations on, (115) 2010
  - transfixion of, by hatpin without injury to lens, (63) 909
  - ulcers, treatment of, (107) 412
- Corns, carbon dioxid snow for, (99) 1658
- Coronary sinus, dilatation of, in mitral stenosis, (118) 828
- Coroner, office of, *842
- Corporeal corrections, chemical, applied to practical medicine, (103) 911
- Corpus callosum, puncture of, to reduce intracranial pressure in 22 cases, (104) 245—ab
  - cavernosum, plastic induration of, (4) 1166
  - luteum abscesses, (48) 823
- Corpuscles: See Blood Cells
- Corrections and Charities, Missouri State Conference of, (56) 1647
- Corrosive Sublimate: See Mercury Bichlorid
- Corset for correction of lordosis causing albuminuria, (138) 1912
- Corsets, orthopedic, and supports, (40) 325—ab
- Cortex, cerebral, circumscribed motor paralysis and cutaneous anesthesia following injury of, (10) 1616—ab
- Coryza and influenza, electric baths in, (133) 168
  - vasomotor periodic, prophylaxis and treatment of, (87) 411
- Council on Pharmacy and Chemistry, report to, on scopolamin-morphin narcosis, *446
- Country, trip to, advantages and disadvantages of, for children of city wage-earners, (34) 746—ab
- Cowpox in man, (15) 1727
- Cows, scarlet fever from, (11) 324
- Coxa valga and coxa vara, traumatic, bloodless correction of, (163) 332
  - vara, (20) 1412
  - vara, static, pathogenesis and etiology of, (66) 166
  - vara, treatment of, (105) 240
- Coxitis, conservative treatment of, (100) 1586—ab
- Cramp, runner's, (41) 740—ab
- Cranial Cavity, Cranium: See Skull
- Craniology, application of, to clinical medicine, (34) 1091
- Craniopagus, frontal, fourth case of, (59) 500
- Cratægus oxyacantha, *103
- Craw-craw, acute, (30) 1483—ab
- Crayons of carbonic-acid ice, blotting paper mold for obtaining, *1519
- Creatin and creatinin, physiology and pathology of, (71) 819—ab
- Creatinin and creatin, physiology and pathology of, (71) 819—ab
  - application of new colorimeter in determination of, (78) 2101
  - excretion of, in infant, occurrence in amniotic fluid, (77) 909
- Crepitations heard in third left intercostal space in mitral stenosis, (8) 1340
  - joint, respiratory, *1865
- Cretinism in Austria, campaign against, (118) 89—ab
  - sporadic; results of thyroid feeding, (107) 162
  - unusual manifestations in, (3) 235—ab
- Cretins, thyroid in, 351—ab
- Cricotracheal stenosis following intubation, (47) 1413
- Crime and heredity, (82) 742—ab
  - influence of physical defects of, (48) 1336
  - what can medical profession do for prevention of? (47) 1336—ab
- Criminal, child, (25) 414
- Criminals, habitual, sterilization of, (29) 237, (29) 320—ab, (26) 414, (23) 565—ab, (103) 568—ab, (46) 1336, (28) 1647—ab
  - hereditary, cure of, (28) 1647—ab
  - juvenile, does correction of physical defects improve moral conduct? (134) 743
- Cripples, non-ambulatory, deformed by infantile paralysis, treatment of, (91) 495
- Crotalin, improved method for administration of, (10) 408
- Cryogenin, action of, on phthisical temperature, (5) 241
- Cubitus valgus, pathologic, (109) 168
- Cuboid, fracture of, (79) 328
- Cullen, (73) 909
- Culture-media, desiccated, (15) 2008—ab
  - reaction of, and morphology of cholera organism, (34) 1336
- Curds, casein, in infants' stools, (99) 495
  - in infant stools, clinical significance of, (19) 651
- Cure at Contrexéville, (25) 822
- Curettage, its abuse and indications, (88) 1337
  - indications and contraindications, (48) 1902
  - of uterus, (23) 1412
- Cyanosis and drop-foot, lymphatic edema of leg and foot with, (11) 2141
  - stasis, from compression of trunk, (54) 1012
- Cyclodialysis, (65) 410
- Cyclophoria, case of, (13) 1172
- Cyst: See also Cysts
- Cyst, abdominal, large, unilateral hematometra of long-standing forming, (35) 325—ab
  - dermoid, with appendicitis, in child, *460
  - echinococcus, in right lung, pneumotomy for, (111) 1178
  - echinococcus, life history of, (34) 1412
  - echinococcus, of liver, (92) 1086
  - formation, periosteal, unusual effect of intracranial pressure, (100) 911
  - formation, relation of parovarium to, (15) 1411
  - intraneural, of eighth cervical nerve, (7) 2140
  - large tumor due to, developing from iliopsoas bursa, *1181
  - of iris, (101) 654
  - ovarian, spontaneous rupture of, (14) 913
  - ovarian, weighing 62 pounds removed from patient aged 80, recovery, (97) 1238
  - pancreatic, (52) 2003—ab
  - parovarian, (128) 496
  - sacrococcygeal, congenital, of ependymal origin, *1288
- Cystinuria, nitrogen metabolism in Raynaud's disease with, (104) 1649—ab
- Cystitis, chronic, in male, treatment of, (91) 2098
  - functional disorders of bladder in women simulating, (38) 2003
  - in women, diseases simulating, (23) 822—ab
- Cystocele, new operative technic to prevent, in vaginal hysterectomy, (34) 739—ab
  - operation with satisfactory results for, (110) 1008
  - vaginal, or preuterine hernia, treatment of, (57) 1176
  - vaginofixation of uterus for cure of, (80) 1580
- Cystoma, colloid, of ovary and colloid degeneration of peritoneum after rupture, (125) 1179—ab
  - polypous, on posterior surface of uterus and other rare findings in internal genitalia, (118) 662
- Cystoscope, practical utility of, for general practitioner, difficulties in its use, (94) 2098
  - study of cerebrospinal fluid in general paresis by, (15) 1646
  - use of, (4) 821
  - with adaptable interposed lenses, (126) 1017
- Cystoscopy and ureteral catheterization in male, (84) 1648
  - in gynecology, (47) 1583
- Cystotomy, suprapubic, interpelvic exfoliation with removal through, (105) 1726
  - suprapubic, with bladder empty, advantages of, (50) 1828
- Cystourethroscope, *1045, (109) 1824
- Cysts: See also Cyst
- Cysts, appendix, and diverticula, (63) 166
  - dermoid, intracranial, (33) 1728—ab
  - echinococcus, seroreaction with, (70) 659
  - echinococcus, toxicity of, (70) 1908—ab
  - improved technic for removal of, (113) 1408
  - in prostate, (33) 1241
  - infundibular, in brain, study of, (123) 1659
  - intramural, of uterus, (30) 1654—ab
  - multilocular, of jaws, (53) 740
  - non-parasitic, in liver, (149) 421
  - of thyreoglossal origin in floor of mouth, (105) 2010
- Cysts, pancreatic, pathogenesis of, (146) 1018
- Cytosine, salts of, (182) 1652

Meniscus, knee, injury of, operative treatment of, (97) 750—ab
  knee, traumatic lesions of, (45) 1655
Menopause, analysis of 200 cases, (99) 1008—ab
  functional disturbances of glands with internal secretion at, (172) 170
  changes in walls of arteries during or preceding, due to disturbances in internal secretions, (94) 1486
  hemorrhages at, (102) 495—ab
  natural and artificial, (15) 913
  pathologic, treatment of, (72) 239-ab
  premature, (55) 741—ab
  treatment of uterine myomas at, (49) 326—ab
  vicarious epistaxis in, (92) 1648
Menorrhagia requiring hysterectomy, (145) 912
Menses, blood pressure between, (61) 500
  retained, relieved by operation, (16) 497
Menstrual changes in blood, (124) 1096—ab
  disturbances, balneotherapy in, (67) 1585
  disturbances following administration of diphtheria antitoxin, *1518
  life, changes in normal endometrium during, based on study of 100 cases, (56) 740
Menstruation and epilepsy, (70) 1007-ab
  and successive menstrual epochs, modifications in typhoid under influence of, treatment, (121) 1009-ab
  coagulation of blood during, (123) 1096—ab
  sign of abortion of an ovum, (37) 415
  variations of temperature in pulmonary tuberculosis during, (5) 1172—ab
Mental aberration following mastoid operations, (135) 820—ab
  and gastric derangement, connection between, (107) 502—ab
  and nervous diseases in Russo-Japanese war, (154) 913
  and nervous diseases, institutional treatment of, *1919
  and nervous *manifestations of pellagra,* (132) 1339
  cases, borderland, (105) 1480
  defectives, study of eye in, *1287
  derangements after infectious disease, (146) 82
  diagnosis, (26) 158—ab
  disease, administration of sodium nucleinate to induce therapeutic hyperleucocytosis in, (41) 823
  disease, localization of cerebral function based on clinicopathologic study of, (1) 1482—ab, (7) 1582, (1) 1652—ab
  disease, physical basis of, (36) 1823
  disease, study of, from standpoint of military surgeon, (55) 2096
  diseases, problems in treatment and prevention of, (79) 568—ab
  disorder, cases of, (3) 1089
  disturbances, emotions as cause of, (53) 2100—ab
  hygiene, (26) 242
  manifestation due to arteriosclerosis, (112) 1338
Mental phenomena, peculiar, (149) 912—ab
  suggestion, philosophy, therapeutic value and present status of, (156) 1826
  symptoms in fatal poisoning by coal-gas from geyser, (13) 2141
  therapeutics, limitations of, in treatment of disease, (42) 409
Menthol in pulmonary tuberculosis, (76) 1177—ab
  treatment of screw-worm, *50
Mercury and arsenic, injection of salts of, during reaction period following tuberculin injections for tuberculosis, (6) 2139—ab
  and arylarsonate treatment of syphilis, (7) 413
  and iodin, action of, in experimental syphilis, (72) 1656
  and tabes-dorsalis, (60) 652
  arsacetin-quinin treatment of syphilis, unsatisfactory experiences with, (122) 828
  and Wassermann reaction, (91) 1732
  bichlorid, an antiseptic, uselessness, damage and dangers of, (61) 567
  bichlorid, inhibition of Wassermann reaction by, (116) 1487
  bichlorid, intravenous injections of, in puerperal fever, (149) 1420
  bichlorid, poisoning by, through vaginl douche, *1867
  blood' in inherited syphilis and its modification under, (32) 746
  chlorid and acetic acid test for bile pigments in stools, (55) 85
  concentration of hydroxyl ions in *pathologic blood and influence of, (120) 1347*
  in tuberculosis, (7) 158, (2) 1166, (99) 1238—ab
  influence of, on Nylander's reaction, (186) 1652—ab
  influence of, on Wassermann reaction, (149) 1912
  intramuscular injections of, in syphilis, (38) 1412
  intravenous injections of, in varicose veins in leg, (54) 1584—ab
  iodids, advantages of moist precipitates of, in eye lesions, (114) 1346
  iodids and arsenic, (30) 1578
  lead and zinc salts injected into vein in ear, changes in rabbit *aorta under influence of,* (117) *1016*
  oxycyanid in syphilis, (121) 1096
  poisoning, *1203
  poisoning, acute, anatomic changes in salivary glands with, (82) 87
  salicylate, hypodermic injections of, in syphilis, (108) 1580
  treatment and seroreaction, connection between, in syphilis, (101) 1178
  use of, by ophthalmic surgeon, (86) 411
Merycism, case of, (25) 1827—ab
Mesentery and intestines, anatomic anomalies in, (72) 1094
Mesentery and small intestine, research on *anatomy* of, (53) 1176-ab
  experimental occlusion of blood vessels of and intestinal stenosis, (177) 170
  hematoma in, (48) 1092—ab
  lipoma in, (151) 1420
  sclerosis of, and varicosity of peritoneum, *351
  traumatic rupture of, *1865
Mesmer to Freud, review of psychotherapy, (22) 1578
Mesosigmoiditis and sigmoiditis, (10) 1827
Metabolism and modern treatment of diabetes, (27) 2002—ab
  and stools, in chronic pancreatitis, (124) 662
  effect of castration on, (117) 1169—ab
  energy, in pregnant dog, (136) 1481—ab
  experiment on infant after gastroenterostomy for congenital stenosis, (10) 1475—ab
  faulty, results of remineralization in conditions of, such as neurasthenia, (12) 1011—ab
  findings during sudden change *from* years of strict vegetable diet to animal food, (68) 416
  general, and chronic degenerative diseases of eye, action of intermittent x-rays on, (6) 1725
  in Addison's disease, (125) 828
  in alimentary decomposition, (61) 1730
  in diabetes, changes of, (44) 493
  influence of scopolamin-morphin anesthesia on, (54) 1725—ab
  iron, after splenectomy, (98) 1015
  lactic acid in, (39) 1654
  liver, cholelithiasis generally disturbance in, (88) 1731
Metabolism, nature of jaundice and its influence on, (136) 1912
  nephritis as disorder of, (143) 1825
  nitrogen, in Raynaud's disease with cystinuria, (104) 1649—ab
  nitrogen, influence of removal of fragments of intestinal tract on, (108) 1238—ab
  nitrogen, *in pernicious vomiting* of pregnancy, (57) 652—ab
  nuclein, pathology of, (84) 1344
  of development, (136) 1481—ab
  of lime, phosphorus, nitrogen and fat, influence of phosphorus, cod liver oil and sesame oil on, in rachitis, (127) 828—ab
  of pyrimidin derivatives, (134) 1480
  of uterus, (64) 500
  protein, in pneumonia, (56) 1725-ab
  protein, influence of removal of segments of gastrointestinal tract on character of, (130) 240—ab
  protein, in typhoid, (99) 321—ab
  purin and purins, of human fetus and placenta, (128) 82—ab
  purin, in infants, (81) 1657
  purin, of monkey, (116) 1169—ab
  research on, to determine influence of salts on infant organism, (82) 1657
  respiratory, and respiration during pregnancy, (75) 1909
Metacarpal, first, fracture of base of, (76) 1829
Metallic sounds in ileus, mechanism of, (108) 1658
  tractor, historical sketch of Dr. E. Perkins, inventor of, (43) 1823
Metastasis, cancer, by retrograde invasion of lymphatics, *(36) 1728*—ab
  graft, of cancer in laparotomy in*cision, (96) 1830—ab*
  in appendix with mammary carcinoma, (88) 1585
  in carcinoma, (127) 655
  pelvic transplantation, as means of recognition of hopeless abdominal carcinoma, (89) 911
Methyl alcohol poisoning, *1866
  violet fuchsin, morphologic and biologic research on tubercle bacili stained with, (64) 1414
Metric system, simple methods of applying, (58) 1006
Metritis, chronic, fat droplets in muscle cells in, *(74) 1909*
  chronic, hemorrhagic, and endometritis, (134) 247
Mice: See also Mouse
Mice and measles, (67) 1479—ab
  dancing, artificial, (97) 329
  effects of serum on carcinoma in, (9) 1583—ab
  effect of trypsin on cancer, and germ cells in, (124) 81—ab
  findings in central nervous system of, under arsacetin treatment; artificial dancing mice, (97) 329
  in transmission of infectious diseases, (185) 171—ab
  inheritance in, and susceptibility to transplanted tumors, (122) 81
  nature of reaction of tissues of susceptible and non-susceptible, to incurable tumor, (123) 81—ab
  rabbits and man, antipneumococcus immunization of, (83) 418
  resistance produced in, against transplanted cancer by autoinoculation of spleen, (148) 413—ab
  tumors in, spontaneous, and influence of heredity on frequency of their occurrence, (121) 81—ab
  tumors in, spontaneous subcutaneous, histologic structure of, with 5 cases of multiple tumors, (80) 1648
  with tumors, comparative size of organs in, (56) 1584
Microbacillus of acne, cultural characteristics of, (6) 2098
Microbe of measles, does it come from mouse? (67) 1479—ab
  of peripneumonia in cattle, (51) 1908
Microbes, action of, on tuberculin, (53) 1908
  passage of, through intestinal wall in experimental strangulation, (59) 243
  rôle of, (52) 165
Microbic infection, early, genesis of non-infectious chronic diseases of middle and later life from, (48) 2096
Micrococcus catarrhalis infection, (39) 498
  tetragenus in septicemia and mixed infections, (109) 1658
Microfilaria diurna and filaria loa, (25) 1091
  in blood of horse at Khartoum, (13) 1827

Pubiotomy and extraperitoneal Cesarean section, (90) 167—ab
  in five cases, (63) 1908
  justification of, (104) 751—ab, (3) 1340—ab, (24) 1412, (35) 2003
Public and physician, (144) 323, (104) 654, (142) 1010, (88) 1480
  Health and Marine-Hospital Service, activities of, in relation to scientific investigations, (118) 323
  Health and Marine-Hospital Service, Army and Navy, relations between, under limitations of existing law, (132) 913
  Health and Marine-Hospital Service, duties of, (133) 913—ab
  juvenile, health education of, (44) 1406—ab
Puerperæ, origin of accessory breasts and ductless axillary mammary glands in, (70) 2101
Puerperal disease, importance of, in pathology, (109) 1487
  fever, blood findings in prognosis of, (54) 326
  fever, intravenous injections of mercury bichlorid in, (149) 1420
  fever, prophylaxis of, (130) 1097—ab
  fever, retention of membranes and scraps of placenta as cause of, (131) 247—ab
  infection, (68) 494, (138) 1088, (102) 1824
  infection, attempts to immunize parturients against, (58) 500
  infection, treatment of, (48) 415—ab, (84) 826—ab
Puerperium, acute, non-puerperal peritonitis in, 3 cases of, (75) 2101-ab
  and pregnancy, Alexander-Adams operation during, (180) 170—ab
  and pregnancy, colon bacillus infection of urinary passages in, (56) 1414
  and pregnancy, fibroid tumors complicating, (61) 1236
  and pregnancy, nutritional changes in fibromyoma of uterus incident to, (76) 1903
  and pregnancy, seroreaction in, (55) 1414
  care of child in, (75) 742
  changes in uterine fibromyomas during, (49) 915—ab
  labor and pregnancy, appendicitis complicating, (79) 411—ab
  labor and pregnancy, ovarian tumor complicating, treatment, (28) 1091
  rational, (10) 424—ab
  slowing of pulse during, and its cause, (126) 1832
  special reaction of blood serum in, (106) 577
  sudden death in, from primary thrombosis of pulmonary arteries, (44) 84
Pulse, delay or retardation of, as sign of aneurism, (24) 325—ab
  graphic registration of, (77) 166, (49) 747—ab
  influencing of, by external pressure on blood vessels, (58) 1730—ab
Pulse, irregular, absolutely, (150) 421
  irregular, absolutely, electrocardiogram of, (124) 247
  jugular, venous, in asystole of left side of heart, characteristics of, (40) 1729
  mirror sphygmograph for study of, (79) 1730
  registration of, photographic, (104) 1095
  slowing of, during puerperium and its cause, (126) 1832
  tracings, application and value in practice, (86) 1726
  venous, studies on, (37) 1901
Pump, air, and glass bell in local treatment of neurasthenic sexual impotency, (191) 171
Puncta lacrimalia, doubling of, (90) 820, (128) 1905
Puniness and infantilism, (69) 243
Pupil, dilatation of, due to bellflower, datura arborea, (102) 654
  reaction, induced mydriasis, as test of, (48) 165—ab
Pupillary movements, physiology of, (121) 743
Pupils, behavior of, in infants, (92) 1178—ab
  during health and disease, (31) 158-ab
  symptoms in thoracic aneurism, (35) 1907
  under general anesthesia, (64) 567
Purgatives, bile acids as, (92) 576
  influence of, on peristalsis, (124) 420—ab
  subcutaneous, *344
Purge, preoperative, is routine administration of, defensible? (105) 495
Purin bases of food, in relation to gout, (73) 1730
  bodies in a case of probable thrombosis of hepatic vein, (137) 1018
  content of food, (129) 1488—ab
  ferments of rat, (181) 1652
  metabolism in infants, (81) 1657
  metabolism of monkey, (116) 1169—ab
  nitrogen, estimation of, in urine, (154) 323
Purins, and purin metabolism of human fetus and placenta, (128) 82—ab
Purpura, abdominal, and appendicitis in childhood, (119) 1338
  fulminans, (21) 1341
  hemorrhagica due to benzol poisoning, (75) 909—ab
  Henoch's intussusception with, (12) 1239
  Henoch's, or angioneurotic edema? (14) 414—ab
  Henoch's, with spinal cord symptoms, (172) 1652—ab
Pus and effusions, differentiation of tuberculous pus from, by Millon's reagent, (155) 1489—ab
  cells in blood, appearance of, not pathognomonic for surgical lesions, (60) 748
  in abdominal cavity, (92) 1581—ab
  in antrum, pyemic poisoning caused by, (25) 817
  Tube: See Fallopian Tube and Salpingitis
Putrefaction, intestinal, influence of lactic acid ferments on, in healthy individual, (156) 323—ab
  of albumin, production of atypical proliferation of epithelium by injection of products of, (69) 2008
  toxic and non-toxic, in intestines, (168) 170
Pyelitis, (112) 920—ab
  and appendicitis, (100) 1909
  in infants, (86) 1168
  in pregnancy and its complications, (80) 653
  of pregnancy, postural treatment and lavage of renal pelvis for relief of, (91) 911
Pyelonephritis, acute, due to B. coli, (37) 1907—ab
  in pregnancy, vaccine treatment of, (14) 656—ab
Pyelotomy for removal of calculi in renal pelvis, value of and indications for, (49) 1828—ab
Pyemia, puerperal, surgical treatment of, (2) 82—ab
  rupture of aorta in, (47) 1729
Pyloroplasty, (145) 744
Pylorospasm, (65) 416, (66) 1007—ab, (32, 35) 1167—ab
  differential diagnosis of, *960
Pylorus and cardia, intermittent spasm of, as reflex neurosis with gall-stone disease, (43) 1729—ab
  and duodenum, method of catheterizing, (66) 416
  and esophagus, stenosis of, from action of caustic, (55) 1828
  cancer of, radical operation for, (3) 913—ab, *1608

Pylorus, cancerous and non-cancerous obstruction of, (13) 817
  carcinomata of, symptom complex of pernicious anemia with, (68) 1007
  changes in gastric mucosa after exclusion of, (42) 1729—ab
  exclusion of, shortened technic for, (169) 1834—ab
  exclusion, regurgitant vomiting due to unusual adhesions following gastroenterostomy with, (106) 412
  insufficiency of, cause of chronic diarrhea, (19) 565—ab
  in young infant, favorable outcome of plastic operation on, (38) 1091
  obstruction, fatal cerebral hemorrhage *following gastrojejunostomy* for, (17) 822
  physiology of, (36) 657
  sarcoma of, with tuberculous adenitis, (163) 1489
  Spasm of: See Pylorospasm
  stenosis of, (141) 1097
  stenosis of, congenital, (106) 245—ab, (101) 1016
  stenosis of, congenital, hypertrophic, (28) 908, (30) 1167
  stenosis of, congenital, indications and technic for operation, (48) 2007—ab
  stenosis of, congenital, metabolism experiment on infant after gastroenterostomy for, (10) 1475—ab
  stenosis of, *congenital, perigastric* adhesions simulating, (62) 1579
  stenosis of, congenital, plastic operation for, (38) 1091
  stenosis of, hypertrophic, cyclic or recurrent vomiting with, (20) 1341
  stenosis of, latent, 5 cases of, (108) 1732—ab
  stenosis of, non-cancerous, remote results of gastroenterostomy in, (57) 1828
  stenosis of, tuberculous, (107) 1830—ab
  unilateral exclusion of, (111) 661
Pyocyaneus bacterin, antigonococcus serum and gonococcus bacterin, *status of therapy by,* *258
Pyogenic and streptococcus infection for sarcoma, *1303
Pyopneumothorax and empyema, (68) 86
  *due to inhaled tooth or to perfora*tion of gastric ulcer, drainage, *recovery,* (5) 656
  tuberculous, cured by resection of ribs, (79) 1014, (103) 1586
Pygopagus, Rosa-Josepha Blazek, accouchemen of, (31) 2099—ab
  Rosa-Josepha Blazek, teratologic study of, (32) 2099
Pyorrhea-alveolaris and other conditions causing septic mouths, (25) 657
  opsonic therapy in, (9) 408
  primary external periodental infection and oral sepsis, (33) 498
  vaccine therapy of, (7) 324
Pyosalpinx, causes, symptoms and differential diagnosis of, (29) 409, (25) 2096—ab
  conservative treatment of, (24) 2096—ab
  peritonitis from rupture of, (43) 915—ab, (85) 1168
Pyramidal-tracts, cause of contractures and spasticity in cases showing no demonstrable lesion of, (84) 239
Pyrimidin derivatives, metabolism of, (134) 1480
Pyuria in latent genitourinary lesions, (22) 1476

Q

Quack and legitimate practitioner, (101) *743*
Quadriplegia, infantile, with pneumococcus infection of meninges, (31) 1341—ab
Quarantine, (136) *912*
Quartz mercury vapor lamp, sterilization *of drinking water by* ultraviolet rays from, (69) 1730
Quinin, action on kidneys of long-*continued* small doses of, (97) 1586—ab
  alkaloid, use of, (26) 83
  and cancer, (107) 245—ab
  and malarial fevers, (14) 1727
  and urea hydrochlorate as local anesthetic, (79) 1726
  and urea hydrochlorid, as local anesthetic, *1375, *1940
  blindness, (175) 1652
  effect of, on properties of serum, (164) 1489—ab
  effect on blood of experimental, long-continued small doses of, (152) 1420—ab, (101) 1732—ab
  fatality, (113) 88
Quinin in fever during pregnancy, (30) 2006
  in malaria, (98) 1586—ab
  in malaria, dosage of, (42) 2007—ab
  malaria in prophylaxis, (130) 663-ab
  in pemphigus, (82) 575—ab
  in syphilis, (94) 244—ab
  salve, in whooping cough, applied to nasal mucosa, (112) 1095
  morphology of malarial plasmodia after administration of, in intracorpuscular conjugation, (167) 1089—ab
  retention, localization and fixation of, in various organs, (129) 90-ab
  subcutaneous injections of, in the obese, deep pitting following, (36) 164
  tetanus, (62) 85
  uses and abuses of, in malarial districts, (108) 1581
Quinsy, recurrent, pathology and *treatment of,* (75) 321—ab

R

Rabbit, arterial disease in, experi*mental,* (53) *651—ab*
  blood, changes with age in number of white corpuscles in, (150) 1660
  results of ligation of Fallopian tube in, (31) 1654
Rabbits, *changes induced in blood* of, by living in atmosphere of water gas, (40) 1901
  effect of severing vagi or splanchnics on gastric motility in, (84) *494*
  effect of thyroidectomy on development of active immunity in, (133) 1480
  immunity production in, by inoculation of increasing numbers of living virulent bovine tubercle bacilli, (120) 911
  man and mice, antipneumococcus immunization of, (83) 418
  mechanical and bloodless method of *inducing albuminuria and neph*ritis in, (59) 1828
  production of nephritis in, (112) 419
  syphilis in, (101) 1095, (143) 1097
Rabies, (36) *908*
  complement binding reaction in, *(43) 1901*
  diagnosis and Pasteur preventive treatment of, (35) 908
  from skunk bites, (50) 1336
  history, prevalence and prevention of, and its relation to animal experimentation, *780
  in Canada, (92) 820
  in Indiana, 3 years of, (16) 2140
  virus of, *266

  removal of, from abdomen during laparotomy as source of material for skin grafting, (104) 911—ab
  sterilization by dichlorid of ethylene and iodin, (9) 2140
  syphilids, proliferating forms of, 18
Skin syphilin reaction in syphilitics, (56) 1484
  tannin sterilization of, (128) 1097—ab
  tuberculin injection in diseases of, (121) 412
  reaction tuberculin, (33) 78, (147) 248, (35) 1412, (54) 1478
  tuberculin reaction, laws of, its application in standardization of tuberculin, (61) 1656—ab
  tuberculin reaction in acute serofibrinous pleurisy, (204) 171
  tuberculous diseases of, treatment of, (2) 744
  tumors, pathology and treatment of, (126) 1825
  varnishes, (57) 1006
Skull, cubic capacity of, estimation of, and correlation of size of head to intellect, (33) 1091
  defects, bone plastic operation for, (64) 748—ab, (94) 1580
  defects in congenital, from amniotic adhesions, (88) 918
  fracture of, (103) 743
  fracture of base of, compound fracture of zygoma, hemiplegia due to, osteoplastic flap operation over motor area, recovery, (18) 1578
  fracture of base of, decompression in treatment of, (35) 657
  fracture of, in child, x-ray examination of, (105) 1830
  fracture of, is operation advisable in? (132) 912
  fracture of, peculiar, typical, (98) 576
  fractures at base of, question of operation in, (37) 409
  infant's, traumatic separation of sutures in, (168) 332
  new method of performing operations on, (93) 911—ab
  operations, suction apparatus for keeping field of operation clear of blood during, (101) 1909
  ping-pong-ball indentation of, without fracture, (95) 1580
  surgery, differential pressure procedure for inducing local anemia in, (128) 90—ab
  tourniquet for control of hemorrhage from scalp during osteoplastic resection of, (68) 2003
  trephining of, in cerebrospinal meningitis, with recovery, (68) 1344—ab
  tumor at base of, (120) 1659
  x-ray diagnosis of lesions of, (53) 573—ab
  examination of, with reference to sphenoidal sinus and sphenoethmoidal cell, (40) 914
Skunk bites, rabies from, (50) 1336
Sleeping-sickness, experimental, (96) 418
  treatment of, (18) 656
Sleep, sleeplessness and hypnotics, (58) 160
Sleeplessness, sleep and hypnotics, (58) 160
Sling for head extension, (135) 412
Smallpox and vaccine, Italian research on, (163) 1834
  diagnosis of, (35) 320
  history of prevention of, (27) 2099
  in United States, (161) 1481
  isolation in, compulsory, (61) 1908—ab
  modified, (163) 1171
Smear preparations, new and quick method for staining spirochetes in, *1498
Smoke, inhalation of, and croupous pneumonia, (102) 1487
Snails, possibility of typhoid infection from, (136) 1659—ab
Snake venom, immunity of hedgehog to, and lack of special resistance to ordinary poisons, (146) 330
Snakebite poisoning, (98) 568
Soamin, intravenous injections of, in cerebrospinal meningitis, (17) 656
  recovery from symptoms *of paralysis* under, (16) 656
Soap production, symptom of, and elimination of bases in infant intestine, (80) 1657
Social *diseases, plea* for American association for prevention of, *692
Social-evil, (98) 653, (92) 1408
  and sanitary science, (43) 409—ab
  and venereal diseases, (115) 1087
Sociologist, cost of venereal infection as viewed by, (35) 566
Sodium benzoate, action of, on multiplication and gas *production of* various bacteria, (159) 324—ab
  benzoate and benzoic acid, effects of, 1774
  benzoate, effects of, *759
  benzoate in human organism, fate of, (149) 570—ab
Sodium benzoate *question* and *food* preservatives, (118) 654—ab
  biborate solution, in empyema, pleuritic effusion and hydrocele, *1058
  carbonate, in chronic nephritis, (106) 1480
  citrate, subconjunctival injections of, in glaucoma, (124) 743
  nucleinate, administration of, to induce therapeutic hyperleucocytosis in mental disease, (41) 823
  persulphate for detection of adrenalin, (142) 248
  solutions, history of *injections* of, (10) 2098
Soldiers with wandering mania, epileptic dream-like mental distraction in, (112) 1346
Sore-throat, diphtheritic and simple, (121) 1650
Sound, crunching, xiphisternal, analysis of cases exhibiting, (52) 410—ab
  galloping, epigastric, (60) 916—ab
  perception, subjective and objective sense of, (147) 821
  perception, interpretation of clinical hearing by sensitive hair theory of, (4) 408—ab
Sounds, friction, pericardial, remote *propagation of*, (88) 1820
Soy bean as diet for infants, *1664
Spalding, L. Dr., father of U. S. Pharmacopeia, *1669
Spark gap of static machine, control of, (142) 1481
Spasm, facial, and tic torticollis, diagnosis and treatment, (26) 746
  intermittent, of both *pylorus* and cardia as reflex neurosis with gallstone disease, (43) 1729—ab
Spasmophilia, action of cod liver oil in, (43) 2100
Spasmophilic diathesis and tetany, management of, in Berlin, (143) 1088
  tendency in children over 12, (91) 1486—ab
Spasmus nutans with nystagmus, (23) 1341
Spasms, muscular, due to heat in cooks on Pulman diners, *1517
Spasticity, resection of posterior spinal nerve-roots for relief of, (139) 1170—ab
Specialism, foundations of, (50) 320
  in medicine, (55) 1336—ab
  in medicine, is it overdone? (6) 1646
  in surgery, (73) 1086
  institutional, (112) 1727
Specialist and practitioner, (68) 410, (134) 1088
  payment of commissions by, to general practitioner, (96) 321—ab
  responsibility of, in prevention of deafness, (16) 1166
Species, modification of, from standpoint of modern geology, (74) 574
Specimens, gross and microscopic, teaching of pathology by case system supplemented by, (20) 2140
  microscopic examination of, and conclusions based thereon, (33) 409
Spectacles, efficacy of various glass in *prescribing of*, (22) 1085
Spectrometer, color-perception, new, (13) 241—ab
Spectrum of guaiac test for blood, (78) 1094
Speculum, anal, *124, (149) 1340
  nasal, self-retaining, quadrivalve, (152) 821—ab
Speech, application of new cardinal principle in disorders of, (19) 914
  disturbances, study of, (115) 1581
  operations on tonsils and disturbances in, (90) 750
Spermatic cord, *primary sarcoma of*, (35) 2142
  fluid, ultramicroscopic examination of, (93) 1732
Spermatorrhea, emissions and impotency for which prostate is responsible, (69) 917
Spermatozoids, enumeration of, (9) 2095
Sphincter ani, laceration of, unique case of, *2043
  control, method for attempting to secure, after colostomy, (110) 240—ab
Sphygmograph, Galileo's, (13) 2002
  mirror, for study of pulse, (79) 1730
Sphygmometer, mercury, new form of, (9) 1010
Spina-bifida, (110) 412—ab
  and orthopedic surgery, (97) 1726
Spinal Anesthesia: See Anesthesia
Spinal-cord, abscess *of*, (143) 420
  analysis of lesions involving lower part of, (150) 1098
  apoplexy of, (125) 89
Spinal-cord, central cavity formation in, due to trauma without fracture or dislocation of vertebral column, (91) 568
  circumscribed serous meningitis of, (101) 1408
  compression of, by vertebral neoplasm, mechanism and behavior of reflexes, (95) 1586
  degeneration of, (27) 1412
  hemorrhage of, *1783
  histologic changes in ganglion cells of, in spinal anesthesia, (98) 1830—ab
  lesions, lower, syndromes induced by, (196) 171
  lesions, segmental diagnosis of, (96) 1417
  new principle in operations for localized extramedullary and intramedullary growths of, *1308
  spinal meningitis resembling tumor of, (16) 1011
  symptoms, Henoch's purpura with, (172) 1652—ab
  syphilis of, assuming form of lateral amyotrophic sclerosis, (51) 1655
  tumor, extrusion of, *1308
  tumor observed within 10 days, *behavior of cerebrospinal fluid*, (171) 1652—ab
  tumor, studied from neurologic and surgical standpoints, (28) 2141—ab
  tumor, successful removal of, (86) 501
  tumors, anesthesia and lack of it in diagnosis of, (170) 1651—ab
  tumors, surgical diagnosis and treatment of, *849
  tumors, symptoms in, (12) 1084
Spinal column, gunshot wounds of, (167) 1651
  disease, epidemic of, in Nebraska, *277
  ganglia in children, (80) 749
  ganglion, transplantation of, into brain, (120) 654—ab
  percussion, value of, in diseases of mediastinum, (47) 79
  process, *fracture of*, unique, (27) 1647—ab
Spine, *contusions and distortions of*, consequences of, (52) 1012
  effect of symmetry and asymmetry in lateral curvature of, (128) 412
  fracture-dislocation of, (42) 566
  fracture of, dislocation and compression, treatment of, (66) 748
  fracture of, unique, (27) 1647—ab
  lumbar, *caries of, continuous extension in treatment of*, *1299
  percussion of, in diagnosis of tracheobronchial tuberculous glands in children, (71) 749
  rigid, myogenous types of, (111) 1238
  rotation and torsion of, in reaction *to bending*, (48) 1012
  shape of, and development of curvature, (44) 747
  straight in median line, presentation with, (137) 247
Spirillum found in relapsing fever in Sudan, (25) 164
Spirochæta duttoni in tick, mechanism of infection in tick fever and hereditary *transmission of*, (3) 413
Spirochæta pallida, (48) 915—ab, *1597
  [illegible] of, 924
  [illegible] new-born infants, diagnostic value of search for, (10) 1822—ab
  India-ink method of staining, (145) 330, (77) 918—ab, *1779
  new and quick method *for staining* of, in smear preparations, *1498
  simplified method for obtaining and preparing specimens of, (100) 1087—ab
  staining technic for, (96) 1486, *1498
Spirometer, measurements of chest with tape measure and, (59) 2097
Splanchnics or vagi, *effect of severing, on gastric motility in rabbits*, (84) 494
Spleen, abnormal, blood findings with, (125) 1097—ab
  abscess of, (132) 1097—ab, (125) 1650
  and kidney, remote results of replantation of, (83) 1237—ab
  enlarged, and *ascites, cirrhosis-of-liver* with, pathology of, (84) 1657
  enlarged, and *polycythemia, Raynaud's disease* with, *gangrene of* both toes, amputation of both legs, (103) 1649
  hemorrhage of, treatment of, (53) 1478—ab
  of tuberculous *guinea-pigs*, formation resembling infarcts in, (141) 420
  patches of sclerosis in, (163) 170
  physiopathology of, (149) 1018
  resistance produced in mice against transplanted cancer by autoinoculation of, (148) 413—ab
  sarcoma of, primary, *453

Spleen, splenectomy for traumatic rupture of, (104) 1087—ab
  supplementary, herniotomy, strangulated hernia found in great omentum at operation, (29) 325
  surgery of, principles underlying, *14
  transplantation of, (46) 1342—ab
Splenectomies, *14, (114) 661—ab
Splenectomy for traumatic rupture of spleen, (104) 1087—ab
  in splenic anemia, recovery, (124) 1650—ab
  iron metabolism after, (98) 1015
  tolerance for various sugars in animals after, (202) 171
Splenization of lung, multiplicity of pathologic anatomic changes in pneumonia with, (60) 1656
Splenomegaly, cirrhosis of liver and ascites, (143) 1018
  with cirrhosis of liver, (111) 88, (166) 1489
Splenomyelogenous leucemia in Igorrote, *1443
Splint, for fractured ulna, *283
  plaster, reinforced, (103) 1168—ab
Spondylitis deformans, (5) 564
  tuberculous, operative treatment of, (75) 500
Sponge perforating into bladder, syndrome induced by, (125) 1017
Sponges, iodin complex in, (149) 323
Spores in schizomycetes, demonstration and study of, (17) 2141
  staining technic for, (95) 1732
Sporothrix, arthritis due to, (42) 1413—ab
  schenckii, seroagglutination of, (96) 573
Sporotrichosis, (58) 85
  actinomycosis and thrush, agglutination and seroreaction in, (34) 1174—ab
  diagnosis and treatment of, (116) 828
  history of, (169) 1490—ab
Sports, influence of, on vital capacity, (71) 166
Sputum, albumin reaction in, (72) 1829—ab
  and blood, improved methods for examination of, in tuberculosis, (138) 496, (153) 570—ab
  tubercle bacilli in, antiformin for detection of, (145) 1488, (136) 1825
  tubercle bacilli in, detection of, (83) 244, (131) 663, (81) 918, (136) 1825, (22) 2141
  tubercle bacilli in, granular form of, (144) 330
  tubercule bacilli in, in pulmonary disease, (72) 917
  swallowed in stool, tubercle bacilli in feces from, (91) 750
Squeal, respiratory, substernal, hitherto undescribed adventitious chest sound heard over region of heart, (72) 1824—ab
Squirrel, rock, susceptibility of, to plague, (84) 2004
St. Andrew's Ambulance Association, formation and early days of, (42) 657
St. Luke the physician, (2) 491
Stage, indeterminate, (34) 1235
Stahl, (73) 909
Stain, for spirochetes, technic of, (96) 1486
  Gram, of feces in pellagra, (100) 1824
  iodin, carbol-fuchsin, for structure of true acid-fast bacteria, (87) 1909
  Neisser, simplified, for diphtheria bacilli, (99) 1417
  rapid, for frozen sections, 1614
Staining, azure-eosin, of sections, (83) 1485
  fuchsinophile and gramophile forms of tubercle bacilli, simplified method of, (12) 1646—ab
  of fat tissue, chemical and histologic research on, (122) 1659
  technic for spores, (95) 1732
  tubercle bacilli, combined technic for, (64) 1656
Stalagmometry, (96) 661
Stammering, can it be treated successfully through agency of public school? *1859
  treatment of, (22) 78, (46) 409—ab
Stapes, accidental removal of, (50) 1167
Staphylo-bacterin in acne, (46) 1578
Staphylococcus albus, experimental guinea-pig infection with, (16) 1406—ab
  aureus, experimental study of opsonic immunity to, (152) 413—ab
  cerebrospinal meningitis treated by specific vaccination, (27) 2006
  immunity and opsonins, (63) 2008
  infection of bladder following carbuncle on neck, (67) 1908
  scarlatinal meningitis, (45) 1175
  sepsis, antistreptococcus serotherapy in, (111) 1417
  prostatitis, stock vaccine in, *126
Staphylococcus rhinitis as cause of folliculitis exulcerans serpiginosa nasi, (74) 320
  septicemia, (136) 1170
  streptococcus, and pneumococcus infections, investigations of serums and vaccines for, *257
Starch with hyperchlorhydria, gastric digestion of, (26) 1583
Starvation, infant, avoidable form of, (60) 1407
  volvulus of empty intestine in, (81) 328
State boards and high entrance requirements, (79) 1479—ab
  federation of women's clubs vs. white plague, (123) 1582
  medical associations and American Medical Association, (46) 1647
  medical society, (83) 321
  municipality, and tuberculosis, (3) 158
  ownership of head waters, (126) 569
  responsibility of, in care of its dependents, (111) 240—ab
Static machine, controlling spark gap of, (142) 1481
Statistical methods, modern, (13) 2006
Statistics, morbidity and mortality, collection of, and control of tuberculosis, (164) 1826
  mortality, trade, (160) 1481
  vital, (88) 1726
  vital, importance of, and their treatment actuarially, (157) 1481
  vital, in Swiss commune, century of, (112) 1910
  vital, of Taytay, P. I., (136) 323
  vital, why important, (152) 1651
Status-lymphaticus, (111) 162
  death under anesthesia due to, *1785
  with sudden death, (9) 241
Steam sterilization, tests for effectiveness of, (42) 2099
Stercobiline, determination of, as aid to prognosis, (65) 1828
Sterility and dysmenorrhea, surgical treatment of conical cervix causing, (51) 84—ab
  and treatment of gonorrhea, *1849
  epididymo-vasostomy for relief of, (85) 411
  etiology of, (23) 1647
  in women, (15) 1901
Sterilization, formaldehyd, by slow combustion of straw, (51) 1092—ab
  of drinking water by ultraviolet rays from quartz mercury vapor lamp, (69) 1730
  of habitual criminals, idiots, and other defectives by vasectomy, (29) 237—ab, (29) 320—ab, (26) 414, (23) 565—ab, (103) 568—ab, (46) 1336—ab, (28) 1647—ab
  of novocain-suprarenin solution, (88) 501

  occult blood in, with trichocephalus, (168) 1834
  of new-born infant, significance of, (55) 1478—ab
  examination of, quick method for, significance for diagnosis and treatment of some intestinal disorders, (5) 738—ab
Stopper for blood-counting pipettes, 467
Stovain and cocain poisoning, ether an antidote of, 904
  anesthesia, *281
  effect of, on nervous system, *1840
  recent use of, in Chicago, (62) 1902
  spinal anesthesia, (89) 1580
  spinal anesthesia, modified technic for, (120) 1017, (73) 1177
Strabismus, family tendency to, (102) 501
Strain, sacroiliac, tendon transfer, double congenital club-foot, (160) 1651
Strangulation, experimental, passage of microbes through intestinal wall in, (59) 243
Straw, formaldehyd sterilization by slow combustion of, (51) 1092—ab
Streptococcemia and sinus thrombosis of otitic origin, (87) 1824
Streptococci, color medium for isolation and differentiation of, (72) 568—ab
  differentiating culture medium for, (131) 1097
  hemolytic, differentiation of, by cultivation in lecithin bouillon, (142) 1420
  homologous, injections of, killed by galactose in treatment of suppurative complications of contagious diseases, (75) 568—ab
  intestinal, from horse, cow and man, comparative study of, (67) 567—ab
Streptococcus and pyogenic infection for sarcoma, *1303
  disease of middle ear with tympanic membrane and perfect hearing, (34) 498
  enteritidis, (63) 1343
  infection and leucocytosis, (89) 660—ab
  infection, puerperal, bacteriologic differentiation of, (87) 1585
  infection, treatment of, (59) 567
  infections of throat, (9) 1724
  of scarlet fever and fixation of complement reaction, (27) 1583
  mucosus capsulatus, chronic suppurative parotitis, caused by, *47
  question, (92) 2009
  staphylococcus, and pneumococcus infections, investigations of serums and vaccines for, *257
  vaccine, in urinary diseases, (79) 1007—ab
  vaccine, scarlet fever prophylaxis with, (12) 907—ab
Streptotrichoses and tuberculosis, (1) 1089—ab, (2) 1171—ab, (1) 1340—ab
  in man with pulmonary involvement, (11) 2140
Stricture, urethral, and its complications, surgical management of, (8) 1334
  urethral, diagnosis and treatment of, (8) 650
Stridor, inspiratory, congenital, etiology of, (69) 327
Strophanthin, *1050
  action of, on artificially lowered blood pressure, (130) 1488
  clinical and experimental study of action of, on cardiovascular system, (109) 418
Strophanthus and digitalis, action of, on frog eye, (121) 1179
Stump of bronchus, care of, after removal of lung, (138) 248
Stuttering, congenital word blindness in school children with, (30-50) 818—ab
Strychnin and novocain, death from intraspinal injection of, (29) 1341—ab
  adrenalin not antidote to, (98) 1178
  in pneumonia of aged, (6) 2002
  new studies of, (127) 1659—ab
  poisoning, *1612
Student, patient, surgeon, and nurse, (12) 1340
Stumps, metal bracelet for fixation of, after fracture of radius, (43) 1413—ab
Subconscious, conception of, (110) 1333
Subcutaneous tissue, atypical proliferation of epithelium after injection of scarlet red oil and amidoazotoluol oil into, (106) 1658
Succussion and taxis, for intussusception, (153) 1010—ab
Sugar, absorption and biologic behavior of different kinds of, in large intestine, (80) 1344
  and lactase, elimination of, in prematurely born infants, (111) 419
  distribution of, in elements of diabetic blood, (63) 1176
  exclusion of, in feeding infants with gastrointestinal disturbances, (94) 576, (111) 1095
Suggestion, (74) 819
  in relation of life-insurance companies to longevity of their policy holders, (5) 1234
  mainspring of hypnotism and psychotherapy, (10) 738—ab
  therapeutics, (115) 654, (119) 743
Suicide, enlarged; parent killing self and children, (105) 1909
  pathologic anatomy of, (125) 1659—ab
Sulphate and nitrogen partitions and test diet in diagnosis of intestinal disturbances, (6) 403

Summer complaints, (122) 1650
Sun blindness, (81) 1015—ab
Sunlight, reflected, curative factor at mountains and seashore, (88) 87
Superstitions, ancient, that still flourish, (27) 325
Supports and orthopedic corsets, (40) 325—ab
Suppositories, nutrient, instead of enemas for rectal feeding, (65) 1656
Suppuration, acute, antiferment treatment of, (11) 656, (105) 1408, (55) 1584
  and inflammation of omentum, (121) 323—ab
  changes in shape of leucocytes during, (111) 577
  in knee-joint, cause and treatment, (27) 914—ab
  in lungs and pulmonary tuberculosis, difficulty of differentiating between, (25) 1583—ab
  of uterine fibroid with unusual manifestations, (59) 1240—ab
  pseudodiphtheria bacillus in, (59) 1012
  typhoid bacillus in development of, (93) 918
Suppurations, bone, (49) 740—ab
  chronic, limitations of bismuth paste in, (116) 1650
  chronic, of nasal and aural cellular spaces, surgical treatment of, (82) 80—ab
  ferments and antiferments in, (11) 656, (105) 1408, (55) 1584
  hyperemia in, in dispensary work, (60) 1648
  mastoid, early diagnosis of, (10) 324
  potassium permanganate in, (114) 1016
  serotherapy of, (93) 1095—ab
Suppurative complications of contagious diseases, injections of homologous streptococci killed by galactose in, (75) 568—ab
Suprarenal cortex, chemical, histochemical and cytologic research on tumors of type of, (120) 1911
  preparations, dosage of, (59) 1176
  treatment, (37) 1241
  treatment, intravenous, in severe cardiovascular collapse, (149) 169
  treatment of gout, (72) 1585
  treatment of osteomalacia,(49)165-ab
  tumor with punctate pigmentation, (124) 1017—ab
Suprarenals and arterial pressure in tuberculous patients, (28) 1241—ab
  and hypophysis, comparative study of effect on blood of extracts of, (104) 2010
  and increased pigment production, connection between, (162) 1913
  cystic, bilateral, (159) 1913
  experimental study of phenomena after removal of, (151) 421—ab
  hemorrhage in, due to chloroform, (68) 1828—ab
  hypoglycemia in dogs after removal of, (125) 662—ab
  influence of diphtheria toxin on, (43) 1583
  pathology of, (87) 418
Suprarenin, synthetic, (155) 1833
Surgeon and physician, (37) 158, (70) 1478
  and physician in appendicitis cases, (108) 412
  anomalies and points to be borne in mind by, (6) 1475
  making of, (141) 569
  patient, student, and nurse, (12) 1340
  responsibility of, in anesthesia, (8) 2095
  when should he be consulted in appendicitis? (31) 1901
Surgeons, army, history of Munich Surgical Institute for, (106) 1346—ab
Surgery, abdominal, in America, early history of, *600
  American, impressions of, (29) 1174
  and general therapeutics in dentistry, *608
  and medicine, (124) 323, (87) 819
  and medicine, Scotland's contribution to, (111) 1825
  and neurology, (65) 166
  antiseptic, beginning of, (101) 568
  antiseptic, modern, *1104
  balsam-oil dressing in, (30) 1235—ab
  blood in, (45) 566—ab
  blood-vessel, and animal experimentation, (86) 2097
  casualty, normal saline solution as dressing in, (111) 1480—ab
  conservatism in, (139) 744
  conservative, in ocular injuries, (95) 1480—ab
  ear, local anesthesia in, (11) 1235
  elements of success in, (21) 492—ab
  emergency, (154) 1340
  exclusion of skin in, (29) 1728
  experimental, aims and tasks of, (64) 166—ab
Surgery, fundamental truths in, (26) 1907
  general, and general medicine, clinical relationship of ophthalmology to, (57) 160
  history and practice of, in ancient and medieval times, (31) 414
  hyperemia in, (7) 907
  in London at beginning of 19th century as observed by American surgeon of old school, (17) 2140
  in Norway, developmentof, (114) 502
  ionic, in cancer of mouth and nose, (73) 1648
  modern, (23) 1006—ab, (45) 1583
  nitrous oxid in, *1589
  of thoracic aorta, experimental, *28, (48) 1584—ab
  original contributions to, *1297
  orthopedic, therapeutic measures successfully used in department of, in Jefferson Medical College, (59) 1648
  progress of, (70) 653
  progress of, in benign conditions of stomach and duodenum, (56) 320
  review of, (95) 568
  rural, coming, (110) 1824
  scientific principle and practical availability of respiration by intratracheal insufflation in, (49) 1583
  specialism in, (73) 1086
  therapeutics a sine qua non in, (99) 81
  two-stage principle in, (46) 566—ab
  use and abuse of, (76) 1580
  uses of catgut in, (2) 324—ab
Surgical celerity, value of, (22) 1006—ab
  diagnosis, (18) 2096
  diagnosis, value of blood examination in, (101) 329
  disease, acute, importance of determining viscosity of blood in, (52) 1584
  diseases and operations, prehistoric, (106) 168
  junk demanding further surgical interference, (108) 569—ab
  technic, (162) 1171
  work, impressions of, in Great Britain and America, (37) 1483
Surra, attenuated, of Mauritius with immunity tests after recovery, (85) 1237
  in camels, treatment of, (57) 1908
Suture, double figure-of-eight, *1500
  importance of, in asepsis, (148) 1098
  material, unabsorbable, or catgut? (96) 576—ab
  tendon, reliable, *1371
Sutures, unpedunculated flaps to insure healing of, (73) 825—ab
Sweats in tuberculosis, efficacy of camphoric acid in, (146) 1420—ab
Swiss commune century of vital statistics in, (112) 1910
Sydenham, (122) 569
Sylvius, Borelli, Van Helmont, Des Cartes, (108) 322
Symbiosis and bacillus influenzæ (6) 1906
Symmetry and asymmetry, effect of, in lateral curvature of spine,(128)412
Symphysis-pubis, rupture of, during delivery, (129) 1832—ab
[illegible] ance of ver- [illegible] primary, of lymph gland in carotid region, (136) 420
Syndrome, cerebellar, from hypertension of cerebral fluid, (65) 1484—ab
  urinary, paradoxical, in epidemic cerebrospinal meningitis, (64) 1484—ab
Syphilids, cutaneous, proliferating forms of, *18
  of nervous system, pathology of, (167) 422
Syphilin reaction, cutaneous and intradermal, in syphilitics, (56) 1484
Syphilis: See also Parasyphilis
Syphilis, (43) 1085
  acquired, deaf-mutism due to, (47) 1908
  acquired, in hereditary syphilitic, (26) 739—ab, (14) 1475
  acquired, of small intestine, (108) 661
  adequacy of treatment of, tested by syphilitic diseases of nervous system, (111) 1904
  adult, of lung, (17) 492—ab
  and idiocy, (153) 169—ab

  plastic closure of gap in, (61) 166
  right, and appendix, anatomic, pathologic and clinical studies of lesions involving, *1491
  supernumerary, in vulva, cure of incontinence of urine from, by resection of kidney, (139) 663—ab
  surgery of, (201) 171
  technic for operations on, in conservative treatment of kidney lesions, (127) 1347—ab
  technic of operations on lower portion of, (32) 492—ab
Ureters, effect of Momburg belt constriction on, (89) 1178—ab
  experimental isolation of, (111) 920—ab
  implantation of, into bladder, (80) 1408—ab
  implantation of, into rectum by sacral route, (4) 2098—ab
  management of, in abdominal pelvic operations, (21) 2006
Ureterocystostomy, improved technic, case of double urethral implantation into bladder, (80) 1408—ab
Ureterolithotomy, combined intraperitoneal and extraperitoneal, advantages of, for calculus in lower ureter, (65, 78) 80—ab, (111) 1408
Urethra, calculi in, (92) 742
  calculus in diverticulum in, (153) 1420
  catheterization of, retrograde, (42) 1175—ab
  stricture of, (37) 1174—ab, (43) 1406
  distention of, some technical difficulties in, in treatment for hypospadias, (109) 329
  in chronic urethritis, cytology of, (52) 658
  in women, tumors of, (57) 410—ab
  large vesical calculus attached to catheter in, removed by suprapubic method, (7) 2095
  male, stricture of, (20) 408—ab, (20) 1006
  male, stricture of, dilatation of, *29, (85) 1480
  operations in women, *1606
  penile, primary epithelioma of, (18) 571—ab
  posterior, pathology of, (40) 1174
  prostatic, complete transverse rupture of, (65) 567
  prostatic, dilatation of, in hypertrophy of prostate, (118) 1831—ab
  rupture of, and contusion of bladder, (63) 824

Water *in obesity, (72) 1014—ab*
  sterile, provision of, for hospitals, (103) 751
  supplies of Illinois and typhoid, (148) 1481
  supply and geology of Taytay, P. I., (130, 131) 323
  supply and sewerage, (29) 2002
  supply and sewerage of lake-shore towns of Lake County, (58) 652
  supply, double, limited outbreak of typhoid due to, (152) 1481
  supply, Ohio river, incident to slack water *navigation*, *hygienic* aspect of, (39) 409
  supply, polluted, necessity for filtration of, (114) 1338
  supply, public, how not to request examination of, (28) 2002
Waters, acid-fast organisms in, (3) 1405—ab
  and serums, mineral, radioactive, (54) 416
flowing, retention of vitality of tubercle bacilli in, (23) 2141
  head, state ownership of, (126) 569
  thermal, Vichy, therapeutic indications for, *(125) 1831*
Weighing, systematic, importance of, in medical treatment, (68) 1730
Weight after birth, normal decline in, (69) 659
  and height, importance of comparing curves of, in infants and weakly children, (124) 329
  standard, restoring with pure milk diet, in cure of movable kidney, (79) 161—ab
Welch dinner, **1218*
Wertheim's operation, followed by uremia, (30) 1091
Whooping-cough, (67) 1236
  abdominal massage in, (65) 1242—ab, (93) *1486*—ab
  diagnostic value of leucocytosis in, *(14) 1906*
  pathology and treatment of, (75) 1585
  treatment of, (53) 825
  treatment of, with quinin salve applied to nasal mucosa, (112) 1095
Wine from inundated wine cellars, is *it a safe drink?* (42) 1012—ab
Wisconsin, transactions of the sixty-*third* annual meeting of State Medical Society of, (38) 493—ab
Woman, aneurism in, (8) 821
  defects in development in, (69) 417—ab
  in medicine, (37) 1406
Woman of 29, severe diabetes mellitus in, recovery, (64) 917
  old, successful rhinoplasty in, (15) 1653
  pregnant, plea for early, frequent and thorough examination of, (116) 412
  rapid and effectual action of serotherapy in acute gonococcus infection in, (39) 415—ab
  young, toxic amblyopia of diabetic origin in, (115) 1480
Womanhood, conservation of, (123) 1480
Women, allowing, to get up early after operation or delivery, and thrombosis and embolism, (99) 88—ab
  as life-insurance risks, (31) 1235, (15) 1582
  bladder calculi *in diverticula* in, (129) 1659
  diseases simulating cystitis in, (23) 822—ab
  elderly, genital prolapse in, treatment of, by bridging vagina, (28) 2099—ab
  effect of venereal diseases on, (110) 1087—ab
  European, in Africa, excessive liability of, to trypanosomiasis, (17) *497*
  functional disorders of bladder in, simulating cystitis, (38) 2003
  glycosuria in, (89) 167—ab
  gonorrhea in, diagnosis and treatment, (23) 1173, (41) 1907
  gonorrhea in, treatment of, (51) 658, *(39)* 818
  intraperitoneal hemorrhages from pelvic organs in, indistinguishable from hemorrhage of extrauterine pregnancy, (118) 1008
  ministering, (19) 2002
  mistakes in diagnosis relating to urinary tract in, (61) *1579*
  nulliparous, dysmenorrhea in, without gross pathologic lesions, (36) 2003—ab
  postgraduate medical work for, in Europe, (127) 1480
  pregnant and non-pregnant, fibroma uteri in, (57) 1902
  pregnant, diabetic, necessity for exclusively dietetic treatment of, (128) 829—ab
  proposed compilation of data for protection for, at childbirth, (160) 1833
Women, proptosis of left broad ligament cause of chronic constipation *with abdominal pain in, (77)* 15580—ab
  relation of infant mortality to occupation and long hours of work for, (123) 1088—ab
  sterility in, (15) 1901
  tumors of urethra in, (57) 410—ab
  urethra *operations in*, *1606
  what they should know of uterine cancer, (70) 160, (23) 320—ab
Wool, pure animal, in medical and *surgical work, (15)* 163
Word-blindness, congenital, as cause of backwardness in school children, case *associated* with *stuttering*, (30-50) 818—ab
  congenital, etiology of, (35) 84
Word-deafness, pure, with autopsy, (98) 911
Work cure, *12
  therapy of, *2032
Workmen, fractured limbs in, treatment of, (5) 821
Workmen's compensation act as it affects medical profession, (21) 1728
  compensation for *industrial* injuries, studies in, (124) 240
Worms, lumbricoid, death from, (149) 1088—ab
Worry, morbid, (119) 1409
Wound, gunshot, of brain, without focal symptoms, (82) 239—ab
  gunshot, surgery of heart, (114) 752
  gunshot, of heart, autopsy findings after, (87) 501
  gunshot, of heart, with recovery, (84) 1007
  gunshot, of heart, without perforation *of pericardium, (119) 1911*
  gunshot, of stomach, treatment of, (111) 1346—ab
  gunshot, of subclavian and brachial arteries, (112) 1016
  gunshot, of toe, (100) 1168
  gunshot, syndrome resembling bulbar paralysis after, (102) 826
  stab, of heart, severe, recovery after, (95) 1345
  stab of liver, pathologic, anatomy of, (52) 2007
  stab, of liver, peculiar course of, (177) 1089—ab
Wounded and sick, care and removal of, on shipboard during and after action, (41) 651
  first aid to, in medical department of ship during action, (44) 651—ab
Wounds, action of antiseptics on, (131) 168
  gunshot, infection of, (69) 1343
  gunshot, of knee, (78) 1829
  gunshot, of spinal column, (167) 1651
  in heart, suture of, (104) 501
  stab, of lungs, operative treatment of, (105) 1732
  therapeutic value of balsam of Peru for, (121) 1911—ab
  treatment of, (134) 241, (119) 654
  treatment of, and results obtained at St. George's Hospital, London, (4) 413—ab
Wrist and finger joints, apparatus for mobilization of, in superheated air, (87) 244

X

Xanthoma result of excess of cholesterin in blood, (19) 2141
Xeroderma pigmentosum, tumor formations and skin lesions in, (116) 81—ab
Xiphisternal crunching sound, analysis of cases exhibiting, (52) 410—ab

Y

Yeast in leucorrhea, (93) 660—ab
Yellow-fever at Martinique, (57) 243, (45) 658
  campaign against, on isthmus of Tehuantepec, (150) 1481—ab
  in Cuba, last epidemic of, (16) 78
  in Mexican republic, (151) 1481—ab
  utility of domiciliary visit in campaign against, (149) 1481

Z

Zadig, method of, in medicine, (38) 651
Zealots, abstinence, total, fundamental errors of, (98) 1486
Zemacol, *1626
Zinc copper fragments embedded in tissues, behavior of, (152) 169
  mercury and lead salts injected into vein *in* ear, *changes in rabbit* aorta under influence of, (117) 1016
Zygoma, compound fracture of, fracture of base of skull, hemiplegia due to, osteoplastic flap operation over motor area, recovery, (18) 1578

CURRENT MEDICAL LITERATURE

INDEX OF AUTHORS

In this Index are the names of the authors of articles which have appeared in THE JOURNAL of the American Medical Association and of articles which have been listed from week to week in the Department of Current Medical Literature as having appeared in other journals. Thus it practically includes the names of all who have published articles in the leading journals of the world during the past six months. To add to its completeness, the names have been added of those who read papers before societies as published in THE JOURNAL. The * preceding the page reference indicates that the article appeared in full in THE JOURNAL. The numbers in parentheses indicate the numbered paragraphs on the pages referred to. The numbers not in parentheses indicate pages.

A

Aaser, P., (144) 830
Abbe, R., (1) 235
Abbe, T., (144) 1088
Abbott, A. W., (33) 1406
